AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: TENNESSEE: Blount Co: Great Smoky Mountains National Park, Gum Swamp in Cade's Cove (35°35'21"N, 83°50'21"W). 9 June 1998. C. Kenneth Dodd, Jr. and Marian L. Griffey. National Museum of Natural History and Great Smoky Mountains National Park photographic archives. Verified by Steve Tilley. Two adults found under logs on the west side of the swamp. Collected 1515–1650 h (air temp 18°C, substrate temp 16°C, relative humidity 77%); Great Smoky Mountains National Park, 3 sinkhole ponds located ca. 1.2 km E Crib Gap on Cades Cove Road (250–300 m downhill [NE] from Finley Cane trailhead) (35°36'38"N, 83°44'39"W). 4 July 1998. C. Kenneth Dodd, Jr. and Marian L. Griffey. USNM 524377–8. Verified by Steve Gotte. Large numbers of larvae found in Sinkhole Ponds 1 and 2. USNM 524378 consists of nine larvae (20.6–24.6 mm SVL, mean = 23.2) collected from rapidly drying Sinkhole Pond 1. USNM 524377 is a single recently transformed juvenile (18.3 mm SVL, 29.5 mm total length) found under cover adjacent to dry Sinkhole Pond 3. Additional larvae (N = 5; 18.8–22.0 mm SVL, mean = 20.0) from Sinkhole Pond 1 are deposited in the collection of Great Smoky Mountains National Park. New Park and county records (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay St. Univ. Center for Field Biol. Misc. Publ. 12:1–94). Extends the range of the Mole Salamander ca. 50 km NE from the nearest known populations in Monroe County, Tennessee, and verifys Huheey and Stupka's (1967, Amphibians and Reptiles of Great Smoky Mountains National Park. Univ. Tennessee Press, Knoxville. 98 pp) speculation that this species eventually might be found within the Park. Collections were made under permits from Great Smoky Mountains National Park (GRSM-98-017) and the Tennessee Wildlife Resources Agency (No. 1103).

Submitted by **C. KENNETH DODD, JR.** and **MARIAN L. GRIFFEY**, U.S. Geological Survey, Florida Caribbean Science Center, 7920 NW 71st Street, Gainesville, Florida 32653, USA.

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: TENNESSEE: Henderson Co: 0.6 km N Jones Road off Rt. 22A (35°36.67'N, 88°26.13'W). 4 May 1998. B. P. Butterfield, B. Britt, and J. Hobbs. Austin Peay State University (APSU 5994). Verified by Floyd Scott. First county record with exact locality data (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay St. Univ. Center for Field Biol. Misc. Publ. 12:1–94).

Submitted by **BRIAN P. BUTTERFIELD, BRYAN BRITT**, and **JEREMY HOBBS**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340-2399, USA.

BOLITOGLOSSA BORBURATA: VENEZUELA: YARACUY: Fila la Guerrillera, Sierra de Aroa. 600 m elev. 10 August 1995. R. Rivero. Museo de la Estación Biológica Rancho Grande, Maracay, Venezuela (EBRG 3173). Verified by Oswaldo Fuentes. First record for state of Yaracuy and outside of the Venezuelan Central Coastal Range. Previous localities were all in the states of Aragua and Carabobo (Brame and Wake 1963, Contrib. Sci. Nat. Hist. Mus. Los Angeles County 69), being at their nearest 100 km E of this record.

Submitted by **CÉSAR LUIS BARRIO A.**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI, Apartado Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve).

NECTURUS MACULOSUS (Common Mudpuppy). USA: KENTUCKY: Kenton Co: Covington, Devou Park, in Prisoner's Lake (39°04.996'N, 84°32.133'W). September 1996. D. McCoy and R. Lohre. Cincinnati Museum of Natural History Herpetological Photographs (CMNH HP4–8). Verified by William S. Bryant. First specimen from county since 1933; previous specimen from Baker Hunt Foundation Museum lost (Kentucky Amphibian and Reptile Museum Voucher Database at the Thomas More College Ohio River Biological Field Station).

Submitted by **RICK G. LOHRE, DEAN R. McCOY**, and **JOHN W. FERNER**, Department of Biology, Thomas More College, Crestview Hills, Kentucky 41017, USA.

NOTOPHTHALMUS VIRIDESCENS LOUISIANENSIS (Central Newt). USA: TENNESSEE: Henderson Co: 0.6 km N Jones Road off Rt. 22A (35°36.67'N, 88°26.13'W). 4 May 1998. B. P. Butterfield, B. Britt, and J. Hobbs. Austin Peay State University (APSU 5995). Verified by Floyd Scott. New county record (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay St. Univ. Center for Field Biol. Misc. Publ. 12:1–94).

Submitted by **BRIAN P. BUTTERFIELD, BRYAN BRITT**, and **JEREMY HOBBS**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340-2399, USA.

THORIUS MINYDEMUS (Minute Pigmy Salamander). MÉXICO: VERACRUZ: 6 km ENE Chiconquiaco, on Microondas Road "Loma Alta," (19°45.29'N, 96°46.97'W), 2160 m. 16 October 1997. M. García-Paris, G. Parra, and D. B. Wake. MVZ 229269. Verified by D. B. Wake and J. Hanken. Range extension of 25 km NE (by air) from vicinity of La Joya (19°38.08'N, 97°09.13'W) (Hanken and Wake 1998. Copeia 1998:312–345). This report represents the northernmost locality for the genus *Thorius*.

Submitted by **G. PARRA-OLEA**, and **M. GARCIA-PARIS**, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA.

ANURA

ACRIS CREPITANS CREPITANS (Northern Cricket Frog). USA: TENNESSEE: Chester Co: 2 km E Jacks Creek off McAdams Road (35°28.02'N, 88°29.74'W). 26 March 1998. B. P. Butterfield, R. Sharp, and M. Williams. Austin Peay State University Museum of Zoology (APSU 5996). Verified by Floyd Scott. New county record (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay St. Univ. Center for Field Biol. Misc. Publ. 12:1–94).

Submitted by **BRIAN P. BUTTERFIELD, RACHEL SHARP**, and **MELISSA WILLIAMS**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340-2399, USA.

BUFO CAMPBELLI. (Campbell's Forest Toad). HONDURAS: Departamento de Gracias a Dios: ca. 30 km south of Mocorón. 10 June 1997. C. J. Franklin and J. Franklin. UTA-A 50474. Verified by J. A. Campbell. New departmental record (Meyer and Wilson 1971. Los Angeles Co. Mus. Nat. Hist. Contr. Sci. 218:1–47).

Submitted by **CARL J. FRANKLIN**, Dallas Zoo Department of Herpetology, 650 South R. L. Thornton Fwy (I-35), Dallas, Texas 75203, USA (e-mail: HERPKING@ix.netcom.com) and **JACQUELINE FRANKLIN**, Louise Wolf Kahn Elementary School, 610 Franklin Avenue, Dallas, Texas 75211, USA.

BUFO CAMPBELLI (Campbell's Forest Toad). BELIZE: STANN CREEK DISTRICT: Sabal's Cassava Farm, 9 km S Dangriga on the Southern Highway. 15–23 March 1998. Omar Attum. University of Louisville Museum (UL 10002). Verified by Peter Sherman. *Bufo campbelli* has been confused with *B. valliceps* (Mendelson 1994, Occ. Pap. Mus. Nat. Hist. Univ. Kansas 166:1–21) and as a result, its true distribution in Belize is not known (Meyer and Foster 1996, A Guide to the Frogs and Toads of Belize. Krieger Publ. Co., Malabar, Florida. 80 pp). Mendelson (1994, *op. cit.*) suggested that *B. campbelli* is restricted in Belize to areas of primary rainforest in the Maya mountains of the Toledo district. The Stann Creek record was found in a cultivated area where cassava and citrus are grown. This record documents a new district record and refutes earlier claims that this toad is restricted to primary rainforests on low mountain slopes.

Submitted by **OMAR ATTUM**, Department of Biology, University of Louisville, Louisville, Kentucky 40292, USA, and **PERRY EASON**, Department of Biology, University of Louisville, Louisville Kentucky 40292, USA.

BUFO COGNATUS (Great Plains Toad) USA: ARIZONA: Coconino Co: North of Williams, Robinson's Dam, Cataract (= Havasu) Canyon. 20 July 1938. M. A. Wetherill. Museum of Northern Arizona (MNA 2773). Verified by Charles H. Lowe. First record for Grand Canyon National Park area (Miller et al. 1982, Amphibians and Reptiles of the Grand Canyon National Park. Grand Canyon Nat. Hist. Assoc. Monogr. No. 4. 144 pp.). Fills gap between eastern Coconino County, Arizona and Clark County, Nevada (Krupa 1990, Cat. Amer. Amph. Rept. 457.1–457.8).

Submitted by **DAVID A. ROSS**, Herpetology Laboratory, Department of Biological Sciences, Campus Box 8007, Idaho State University, Pocatello, Idaho 83209-8007, USA.

COCHRANELLA GRANULOSA. HONDURAS: OLANCHO: Quebrada de Las Marías (15°18'N, 85°21'W), 680 m elev. 3 August 1998. J. R. McCranie, K. L. Williams and L. D. Wilson. USNM 529986. Verified by J. M. Savage. First record for country; extends range ca. 160 airline km N of the site at 3 km SE Ayapal at Río Curinwas, Departamento de Jinotega, Nicaragua (Köhler and Seipp 1998, Natur und Mus. 128:170–175).

Submitted by **JAMES R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157-2933, USA, **LARRY DAVID WILSON**, Department of Biology, Miami-Dade Community College, Kendall Campus, Miami, Florida 33176, USA, and **KENNETH L. ELACHISTOCLEIS BICOLOR. ARGENTINA: CÓRDOBA: Barreto (33°20'43"S, 63°18'20"W, 153 m elev.), Km 148, Ruta provincial No. 4. 9 March 1999. A. L. Martino. Herpetological Collection of Universidad Nacional de Río Cuarto, Ecología (UNRC ECO637–638). Verified by R. Martori. New locality record, previously known only from one locality in Córdoba Province (Río Calamuchita, Villa María) (Gallego and Giménez 1998, Cuad. Herp., 12[1]:49). Extends range 105 km S in the center of Argentina. The two males (SVL 28 mm and 29 mm) were collected while they were calling in a temporary pond in the afternoon.

Submitted by **ADOLFO L. MARTINO**, **SUSANA JIMÉNEZ TEJEDOR,** and **ISMAEL E. DI TADA**, Ecología, Departamento de Ciencias Naturales, Facultad de Ciencias Exactas, Físico-Químicas y Naturales, Universidad Nacional de Río Cuarto, Km 601, Ruta Nacional No. 36, (5800) Río Cuarto, Córdoba, Argentina (e-mail [ALM]: amartino@exa.unrc.edu.ar).

ELEUTHERODACTYLUS PLANIROSTRIS (Greenhouse Frog). USA: FLORIDA: Franklin Co: W edge Apalachicola along Rt. 98. 25 December 1998. K. J. Irwin, L. Irwin, N. Weaver, S. L. Collins, and J. T. Collins. KU 288624–627. Verified by Joseph T. Collins. New county record and first record of this alien species within the Apalachicola lowlands of the Florida panhandle (Conant and Collins 1998, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third edition expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.).

Submitted by **KELLY J. IRWIN**, Museum of Natural History, University of Georgia, Athens, Georgia 30602-1882, USA (e-mail: kjirwin@arches.uga.edu).

ELEUTHERODACTYLUS PLANIROSTRIS (Greenhouse Frog). USA: FLORIDA: Franklin Co: Timber Island, SW of Carrabelle. 7 March 1999. K. L. Krysko and A. T. Reppas. Verified by David Auth. Florida Museum of Natural History, University of Florida (UF 117393). New county record and second record of this non-indigenous species within the Apalachicola Lowlands in the Florida panhandle (Conant and Collins 1998, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third edition expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.).

Submitted by **KENNETH L. KRYSKO**, Department of Wildlife Ecology and Conservation, and Florida Museum of Natural History, Division of Herpetology, University of Florida, Gainesville, Florida 32611, USA (e-mail: kenneyk@flmnh.ufl.edu), and **ANTHONY T. REPPAS**, Florida Museum of Natural History, Division of Herpetology, University of Florida, Gainesville, Florida 32611, USA.

***GASTROTHECA OVIFERA*:** VENEZUELA: YARACUY: Los Bacos, Sierra de Aroa. 1600 m elev. 21 April 1996. R. Rivero. Museo de la Estación Biológica Rancho Grande, Maracay, Venezuela (EBRG 3325). Verified by G. Rivas. First record for the state of Yaracuy, 100 km W from previous localities known in other northern states: Aragua, Carabobo and Distrito Federal (Rivero 1961, Bull. Mus. Comp. Zool., 126[1]), all in the Venezuelan Coastal Range. This record constitutes the first locality outside of this mountain range.

Submitted by **CÉSAR LUIS BARRIO A.**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI, Apartado Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve).

GASTROTHECA WALKERI: VENEZUELA: YARACUY: Hacienda El Jaguar, 15 km NNW Aroa, La Horqueta. 13 April 1994. R. Rivero. Museo de la Estación Biológica Rancho Grande, Maracay, Venezuela (EBRG 2744). Verified by G. Rivas. First record for the state of Yaracuy. Previously known only from a few localities in Distrito Federal and Aragua (Duellman 1980, Occas. Pap. Mus. Zool. Univ. Michigan 690:1–7) in the central Venezuelan Coastal Range. This record constitutes an extension of the range of the species 140 km W of previous localities known, and the only record outside of the Venezuelan Coastal Range.

Submitted by **CÉSAR LUIS BARRIO A.**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI, Apartado Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve).

HYLA LANCIFORMIS. (Rana Lanceolada Común, Lancehead Treefrog). VENEZUELA: TÁCHIRA, Represa Uribante,1100 m elev. 5 July 1985. R. Pérez. Colección de Vertebrados, Facultad de

Ciencias, Universidad de los Andes, Mérida, Venezuela (CVULA 3858). Verified by O. Fuentes; Quebrada Honda, Potosí. No date (CVULA 3307). Grupo de Ecología Animal. Verified by D. Torres; La Alcantarilla, Uribante. 18 July 1985. (CVULA 3860). Proyecto Uribante-Caparo, ULA. Verified by L. F. Navarrete. *Hyla lanciformis* was known to have a distribution in Venezuela similar to that of *Hyla lanciformis guerreroi*, based on specimens from Guatopo, Estado Miranda, in the north-central part of the country. McDiarmid and Paolillo (1988, *In* Brewer Carías (ed.), Cerro de la Neblina, Resultados de la Expedición 1983–1987. FUDECI, Caracas) reported the nominal form from the River Baría at the S edge of Estado Amazonas, indicating that voucher specimens from that area were deposited in the American Museum Natural of History, New York (AMNH), United States National Museum of Natural History, Washington, D.C. (USNM), and Museum of Biology of the Central University of Venezuela, Caracas (MBUCV). We located the catalog numbers of these vouchers (MBUCV 131168–69). Péfaur and Díaz de Pascual [1987, Rev. Ecol. Latinoamerica 1(3–4): 9–19] mention this species from the state of Barinas in the Andean piedmont in the western part of the country, but without indicating the catalog numbers of the specimens. The animals to which they referred, collected in La Soledad, Barinas, are deposited in the Colección de Vertebrados, Facultad de Ciencias, Universidad de los Andes, Mérida, Venezuela (CVULA 2138, 2247, 2689, 2719–20). These records increase the distribution of the species about 700 km to the WSW from Guatopo and about 1000 km to the NW of the Río Baría.

Submitted by **CÉSAR LUIS BARRIO A.**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI, Apartado Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve), **ANDRÉS ORELLANA**, Apartado Postal 210, 5101-A, Mérida, Venezuela (e-mail: aorell@ciens.ula.ve), and **ROGER MANRIQUE**, Apartado Postal 210, 5101-A, Mérida, Venezuela.

HYLA SCHUBARTI. BOLIVIA: PANDO: Cobija, Río Acre, Province Nicolás Suárez (11°02'S, 68°46'W). 15 February 1982. C. M. Fugler. USNM 281678–682. Verified by W. R. Heyer. First record for the country. Presence was predicted by De la Riva (1990, Boll. Mus. reg. Sci. Nat. Torino 8[1]:261–319). The nearest record is at Cuzco Amazónico, Peru (69°05'S, 12°35'W) (Duellman and Salas 1991, Occas. Pap. Mus. Nat. Hist. Univ. Kansas 143:1–13).

Submitted by **IGNACIO DE LA RIVA,** Museo Nacional de Ciencias Naturales, C/ José Gutiérrez Abascal 2, 28006 Madrid, Spain.

HYLA WAVRINI (Upper Orinoco Treefrog). BRAZIL: AMAPÁ: Amapá: Fazenda Itapuã (2°03'N, 50°48'W). 7 July 1997. A. K. Péres Jr., D. S. Zamboni, and Guarino R. Colli. Coleção Herpetológica da Universidade de Brasília (CHUNB 02676). Verified by M. T. U. Rodrigues. First record for the state of Amapá; calling from a small tree next to a stream in gallery forest within a large patch of Amazonian Savanna. Extends range ca. 654 km NE from previous eastern limit of distribution (Alter do Chão, near Santarém; Hoogmoed 1990, Zool. Med. Leiden 64[6]:71–93).

Submitted by **AYRTON K. PÉRES, JR.** and **GUARINO R. COLLI**, Departamento de Zoologia, Universidade de Brasília, 70910-900, Brasília, Distrito Federal, Brazil (e-mail: grcolli@unb.br).

PSEUDACRIS CRUCIFER. (Spring Peeper). KANSAS: LINN CO: center Sec. 16, T21S, R25E. 3 April 1999. Joseph T. Collins and Suzanne L. Collins. KU 288677. Verified by John E. Simmons. Discovery of this population corroborates a 63-year old record (KU 20359) collected in the same county on 9 April 1936. Single adult male taken as voucher from a chorus of ± 20 specimens. Other anurans chorusing or present at same site were *Bufo americanus, Hyla chrysoscelis/H. versicolor, Pseudacris triseriata, Rana catesbeiana,* and *Rana sphenocephala.*

Submitted by **SUZANNE L. COLLINS**, The Center for North American Amphibians and Reptiles, 1502 Medinah Circle, Lawrence, Kansas 66047, USA, and **JOSEPH T. COLLINS**, Kansas Biological Survey, 2041 Constant Avenue, Lawrence, Kansas 66047, USA.

RANA CLAMITANS CLAMITANS (Bronze Frog). USA: TENNESSEE: HAYWOOD CO: Hatchie National Wildlife Refuge, Oneal Lake (35°29.96'N, 89°15.89'W). 24 April 1998. B. P. Butterfield, M. Hargreaves, and A. Reed. Austin Peay State University Museum of Zoology (APSU 5995). Verified by Floyd Scott. New county record (Redmond and Scott 1996, Atlas of Amphibians in Tennessee. Austin Peay St. Univ. Center for Field Biol. Misc. Publ. 12:1–94).

Submitted by **BRIAN P. BUTTERFIELD, MICHELLE HARGREAVES**, and **AKEIA REED**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340-2399, USA.

SCAPHIOPUS COUCHII (Couch's Spadefoot) USA: COLORADO: BENT CO: found in town of Hasty, Colorado, following rain (Sec. 25, T22S, R50W, 1185 m elev.). 2 October 1990. The specimen is catalogued as BS/FC 7773 in the U.S. Geological Survey, Biological Survey Collection, in the Museum of Southwestern Biology, University of New Mexico, Albuquerque (USNM 155835). Verified by Stephen Corn. New county record; this locality represents an ENE range extension of ca. 30 miles (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **STEPHEN P. MACKESSY**, Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639-0017, USA, **DEAN E. BIGGINS**, U.S. Geological Survey, Biological Resources Division, Midcontinent Ecological Science Center, 4512 McMurry Avenue, Ft. Collins, Colorado 80525-3400, USA, and **BRIAN MILLER**, Conservation Department, Denver Zoological Foundation, 2300 Steele Street, Denver, Colorado 80205-4899, USA.

SCINAX PERERECA. ARGENTINA: MISIONES: DEPARTAMENTO GENERAL BELGRANO: 30 km E Bernardo de Irigoyen. November 1986. M. Canevari and G. R. Carrizo. Museo Argentino de Ciencias Naturales, Buenos Aires, Argentina (MACN 33042–43). Deseado: Km 2, Ruta Provincial 19. 11 January 1995. J. Faivovich. MACN 36957–59. DEPARTAMENTO GUARANY: San Vicente: Campo anexo INTA "Cuartel Rio Victoria" Ruta nacional 14, Km 1272. 7–20 February 1994. M. López, J. C. Basiluk, and J. Faivovich. MACN 35096–105 and, 5 February 1995, Fundación Miguel Lillo, Tucumán, Argentina (FML 7931–32). DEPARTAMENTO CAINGUÁS: Aristóbulo del Valle: Balneario Cuña Pirú. 6 October 1997. A. Giraudo and R. Abramson. MACN 36833–35. All verified by G. J. Scrocchi. Extend the known range of species (Pombal et al. 1995, J. Herpetol. 29:1–6) ca. 550 km SW and constitute the first records of the species for Argentina.

Submitted by **JULIÁN FAIVOVICH** and **GUSTAVO R. CARRIZO**, División Herpetología, Museo Argentino de Ciencias Naturales "Bernardino Rivadavia," Avenida Angel Gallardo 470 (1405) Buenos Aires, Argentina (e-mail: jfaiv@tecnolab.com.ar).

SCARTHYLA OSTINODACTYLA. BOLIVIA: PANDO: Cobija, Río Acre, Province Nicolás Suárez (11°02'S, 68°46'W). 11 February 1982. C. M. Fugler. USNM 281671. Verified by W. R. Heyer. First record for the country. Presence was predicted by De la Riva (1990, Boll. Mus. reg. Sci. Nat. Torino 8[1]:261–319), because the type locality is only 175 km from Cuzco Amazónico, Peru (69°05'S, 12°35'W) (Duellman and De Sá 1988, Trop. Zool. 1:117–136).

Submitted by **IGNACIO DE LA RIVA,** Museo Nacional de Ciencias Naturales, C/ José Gutiérrez Abascal 2, 28006 Madrid, Spain.

TESTUDINES

CHELONOIDIS (= *GEOCHELONE*) *CHILENSIS* (Chaco Tortoise). ARGENTINA: MENDOZA: San Carlos Department: Villa Chilecito District: Campos Las Aguadas. 2 February 1996. E. Richard. Herpetological collection, Fundación Miguel Lillo (FML 7765). Verified by G. Scrocchi. First record for the department. The species was previously recorded from the departments of Mendoza, Santa Rosa, and San Rafael (Waller 1986, Fundación Vida Silvestre Argentina Amph. y Rept. Conserv. 1[2]:36–48; and Lavalle and Rivadavia, Asoc. Herpetol. Argentina Cuad. Herp. 8[1]:131–140, but not documented by vouchers) and for departments of San Rafael and Lujan de Cuyo (Waller 1986, *op. cit.*, documented with vouchers).

Submitted by **ENRIQUE RICHARD**, Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina and Reserva Experimental Horco Molle, Fac. de Cs. Nat. e IML, Universidad Nacional de Tucumán, casilla de correo 454, 4000 Tucumán, Argentina (e-mail: enrique.richard@tucbb.com.ar).

CHELYDRA SERPENTINA (Common Snapping Turtle). USA: KENTUCKY: Campbell Co: Alexandria, along Wesley-Chapel Road in 12-Mile Creek (38°53.284'N, 84°18.547'W). 5 August 1998. C. Brown, N. Crooker, S. Culman, J. Gels, J. D. Schaeffer, and W. Stamm. Cincinnati Museum of Natural History (CMNH 5721). Verified by Melissa Obermeyer. New county record (Kentucky Amphibians and Reptiles Museum Voucher Database at the Thomas More College Ohio River Biological Field Station).

Submitted by **CHRISTOPHER LORENTZ** and **JOHN W. FERNER**, Department of Biology, Thomas More College, Crestview Hills, Kentucky 41017, USA.

CLEMMYS MUHLENBERGII (Bog Turtle). USA: GEORGIA: Towns Co: 11 km NNE Blairsville. 3 May 1992. Kenneth M. Fahey and Brian Fahey. An adult female (CL = 86.47 mm) was found in a seepage in a cow pasture. Museum of Natural History, University of Georgia, Athens (UGAMNH 40138, color slide). A total of seven adult individuals have been observed at this site. This locality represents a new county record and fills the hiatus between Rabun and Union counties. (Williamson and Moulis 1994, Savannah Sci. Mus. Spec. Pub. No. 3; Esco and Jensen 1996, Georgia Herp Atlas, Matrix of Georgia's Amphibians and Reptiles. Ver. 1.0. Georgia Dept. Nat. Resources, Wildlife Res. Div., Nongame-Endangered Wildlife Prog.). Union Co: 21 km SSW of Blairsville. 7 June 1992. Kenneth M. Fahey and Brian Fahey. Skeletal remains, shell (CL = 41.5 mm) with scutes, hind feet, and tail, of a juvenile (2+ annuli on marginal scutes) found in a sphagnum bog (UGAMNH 40139). Thirteen additional adult individuals have since been observed at this site; extends range of the species ca. 13 km SW of the currently known range in Georgia (Williamson and Moulis 1994, *op. cit.*) and represents the most southerly known point in the geographic distribution of this species (Conant and Collins 1998, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third edition expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.); 7 km NE of Suches. 10 May 1994. Kenneth. M. Fahey. An adult female (CL = 90.63 mm) was found in a sphagnum bog (UGAMNH 40140, color slide). Eight additional adult individuals have since been observed at this site. This locality extends the range of the bog turtle an additional 15.5 km WSW of previously known Georgia localities (Williamson and Moulis 1994, *op. cit.*); 3 km N of Suches. 7 June 1996. Kenneth. M. Fahey. An adult female (CL = 90.75 mm) found in a spring seepage (UGAMNH 40141, color slide). This site is between the above mentioned Union County sites and is separated from both by 2.5 km and 6 km, respectively. Rabun Co: 16 km ENE from Clayton. 15 June 1996. Kenneth. M. Fahey and Douglas Walker. A nearly complete shell (CL = 82.9 mm) of an adult female was found in a sphagnum bog (UGAMNH 40142). The carapace, plastral scutes, and pelvis were still attached to the shell indicating that the remains were relatively recent. The xiphiplastral elements and associated scutes are missing. This represents the third known locality for Rabun County (Williamson and Moulis 1994, *op. cit.*). Prior to this report, only three records, two from Rabun County and one from Union County, existed for the bog turtle in the state of Georgia. These records represent one new county record and four new localities for this taxon in the state of Georgia. All specimens were verified by Dennis W. Herman and John Jensen.

Submitted by **KENNETH M. FAHEY**, 439 Pinewood Drive West, Dahlonega, Georgia 30533, USA.

GRAPTEMYS PSEUDOGEOGRAPHICA OUACHITENSIS (Ouachita Map Turtle). USA: OKLAHOMA: Garfield Co: 11.3 km E Waukomis, Skeleton Creek. Summer 1997. Jerrod Burchart. St. Gregory's University, Shawnee, Oklahoma collection (SGU 707). Verified by Doyle L. Crosswhite. First county record at the extreme northwestern edge of range (Conant and Collins 1998, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third edition expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.).

Submitted by **RICHARD L. LARDIE**, 313 Flintridge Road, Enid, Oklahoma 73703, USA.

KINOSTERNON FLAVESCENS FLAVESCENS (Yellow Mud Turtle). USA: TEXAS: Kenedy Co: Ecino [sic] (King Ranch). 13 April 1991. No specific collector. TAIC 5816. Verified by Steve A. Smith. Ecino is a misspelling of Encino. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **MICHAEL JAMES McCOID**, Department of Biology, Campus Box 158, Texas A&M University, Kingsville, Texas 78363, USA.

TRACHEMYS SCRIPTA ELEGANS (Red-eared Slider). USA: NEBRASKA: Richardson Co: 2 mi N and 0.5 mi E Rulo (T1N, R16E) in an overflow pond along the west side of the Missouri River. April 1994. John Lynch. University of Nebraska State Museum (UNSM 15557). A dozen or more specimens were seen in this 150' by 300' and 10' deep pond. The referenced specimen is a skeleton, collected along the shoreline and represents a new county and state record for the species. *Trachemys s. troostii* (Hudson 1942, The Amphibians and Reptiles of Nebraska. Nebraska Cons. Bull. 24:1–146; Iverson 1992, A Revised Checklist with Distribution Maps of the Turtles of the World. Richmond, Indiana. 363 pp.) has been recorded from Adams County in south central Nebraska based on a mounted specimen in the Hastings College Museum. No addi-

tional specimens have been collected in that vicinity and that specimen probably represents a pet release. *T. s. elegans* has been reported on the eastern side of the Missouri River in Holt County, Missouri (Johnson 1987, The Amphibians and Reptiles of Missouri. Publ. Missouri Dept. Conserv., Jefferson City. x + 368 pp.) as well as in Brown and Doniphan Counties in northeastern Kansas (Collins 1997, Amphibians and Reptiles in Kansas. Third Edition. Univ. Press of Kansas, Lawrence. xx + 397 pp.), so the record in Nebraska is not unexpected.

Submitted by **ROYCE E. BALLINGER** and **JOHN D. LYNCH**, School of Biological Sciences, University of Nebraska-Lincoln, Lincoln, Nebraska 68583-0118, USA.

TRACHEMYS SCRIPTA (Slider). USA: TEXAS: SAN AUGUSTINE CO: DOR female found 800 m east of the Attoyac River bridge on the eastbound shoulder of Texas Rt. 103. 27 April 1999. Daniel Saenz. SFAVM 4893. Verified by Michael B. Keck. New county record (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M Press, College Station, 434 pp.). Specimen was quite damaged and eggs were scattered on the roadway. When this turtle was found, two American crows (*Corvus brachyrhynchos*) were eating the eggs and picking at the carcass.

Submitted by **DANIEL SAENZ** and **CHRISTOPHER S. COLLINS,** Wildlife Habitat and Silviculture Laboratory, Southern Research Station, U.S.D.A. Forest Service, Nacogdoches, Texas 75962, USA.

LACERTILIA

AMEIVA WETMOREI (Wetmore's Ameiva). PUERTO RICO: Isla Guayacan. 25 December 1977. A. Resetar, R. Evers, and M. Evans. Verified by A. Resetar. FMNH 207299–300. First record for island (Heatwole et al. 1981, Atoll Res. Bull. 251:1–63).

Submitted by **GREGORY C. MAYER**, Department of Biological Sciences, University of Wisconsin-Parkside, Kenosha, Wisconsin 53141, USA.

ANOLIS BIPORCATUS (Giant Green Anole). HONDURAS: DEPARTAMENTO DE GRACIAS A DIOS: ca. 30 km south of Mocorón. 10 June 1997. C. J. Franklin and J. Franklin. UTA color slide 22641. Verified by J. A. Campbell. New departmental record (Meyer and Wilson 1973. Los Angeles Co. Mus. Nat. Hist. Contr. Sci. 244:1–38).

Submitted by **CARL J. FRANKLIN**, Dallas Zoo Department of Herpetology, 650 South R. L. Thornton Fwy (I-35), Dallas, Texas 75203, USA (e-mail: HERPKING@ix.netcom.com) and **JACQUELINE FRANKLIN**, Louise Wolf Kahn Elementary School, 610 Franklin Avenue, Dallas, Texas 75211, USA.

ANOLIS CAPITO (Big-headed Anole). HONDURAS: DEPARTAMENTO DE GRACIAS A DIOS: ca. 30 km south of Mocorón. 11 June 1997. C. J. Franklin and J. Franklin. UTA-R 42656. Verified by J. A. Campbell. New departmental record (Meyer and Wilson 1973. Los Angeles Co. Mus. Nat. Hist. Contr. Sci. 244:1–38).

Submitted by **CARL J. FRANKLIN**, Dallas Zoo Department of Herpetology, 650 South R.L. Thornton Fwy (I-35), Dallas, Texas 75203, USA (e-mail: HERPKING@ix.netcom.com) and **JACQUELINE FRANKLIN**, Louise Wolf Kahn Elementary School, 610 Franklin Avenue, Dallas, Texas 75211, USA.

CNEMIDOPHORUS INORNATUS (Little Striped Whiptail). USA: ARIZONA: NAVAJO CO: Petrified Forest National Park (PEFO), SW 1/4 Sec 34, T17N, R23E. 19 June 1998. T. Persons and M. Spille. LACM 144791 and PEFO 14757; APACHE CO: Petrified Forest National Park, NW 1/4 Sec 20, T17N, R24E. 2 June 1998. T. Persons. LACM 144790 and PEFO 14758. Both verified by David Kizirian. Specimens constitute the first records for Navajo and Apache counties, and extend known geographic range ca. 107 km ESE and 138 km SW (Wright and Lowe 1994, J. Arizona-Nevada Acad. Sci. 27[1]:129–157). Specimens appear most similar to *C. inornatus pai* known to the west in Coconino County, Arizona, suggesting that the range may be more continuous in northeastern Arizona.

Submitted by **TREVOR PERSONS,** USGS/BRD, Colorado Plateau Field Station, P.O. Box 5614, Northern Arizona University, Flagtaff, Arizona 86011-5614, USA, and **JOHN W. WRIGHT**, Section of Herpetology, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA.

CNEMIDOPHORUS NATIVO (Brazilian Whiptail). BRAZIL: BAHIA: Prado Municipality, Cumuruxatiba District (17°05'S, 39°10'W), 35 km N Prado city. 3 January 1995. C. F. D. Rocha and H. G. Bergallo. Museu Nacional Nacional do Rio de Janeiro (MNRJ 7047); Alcobaça District, Guaratibas Beach (17°25'S, 39°12'W), 15 km S Prado city. 25 October 1997. C. F. D.Rocha and G. F. Dutra (MNRJ 7048); Nova Viçosa Municipality, (18°00'S, 39°03'W). 6 January 1995. C. F. D. Rocha and H. G. Bergallo (MNRJ 7049). ESPÍRITO SANTO: Itaúnas Municipality, (18°24'S, 39°43'W). 8 January 1995. C. F. D. Rocha and H. G. Bergallo (MNRJ 7050); Conceição da Barra Municipality (19°10'S, 39°45'W). 10 January 1995. C. F. D. Rocha and H. G. Bergallo (MNRJ 7051). All verified by U. Caramaschi. Recently described by Rocha et al. (1997. Herpetologica 53:374–382) and was known only from the type locality (Linhares Municipality, state of Espírito Santo). Extends the range of the species ca. 200 km N along coast from type locality; first documented records for the state of Bahia in northeastern Brazil.

Submitted by **CARLOS FREDERICO DUARTE ROCHA, VANDERLAINE AMARAL DE MENEZES,** and **HELENA GODOY BERGALLO**, Setor de Ecologia, Instituto de Biologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, Maracanã, Rio de Janeiro, 20550-011, Rio de Janeiro, Brazil, and **GUILHERME FRAGA DUTRA**, Projeto Abrolhos 2000, Conservation International do Brasil, Caravelas, Bahia, Brazil.

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner). MÉXICO: TAMAULIPAS: Playa Bagdad and Playa Lauro Villar (25°51.424'N, 97°09.015'W), 35 km E Matamoros, sea level. 14 July 1997 and 29–30 April 1998. D. Jiménez-Ramos, E. Pérez-Ramos, and J. A. Vargas-Contreras. Verified by Adrián Montes de Oca. Museo de Zoología "Alfonso L. Herrera" (MZFC 11178–87). Several authors have suggested that *Cnemidophorus sexlineatus* might be found in northeastern México (Duellman and Zweifel 1962, Bull. Am. Mus. Nat. Hist. 123:155–210; Smith and Dixon 1987, Bull. Maryland Herpetol. Soc. 25[4]:154–157; Wright 1993, *In* J. W. Wright and L. J. Vitt [eds.], Biology of Whiptail Lizards [Genus *Cnemidophorus*]. Publ. Oklahoma Mus. Nat. Hist. 417 pp.; Flores-Villela 1993, Herpetofauna Mexicana. Carnegie Mus. Nat. Hist. Spec. Pub. No. 17:1–97). Corroborates first record for México with a series of 10 specimens collected in halophytic vegetation.

Submitted by **DAVID JIMÉNEZ-RAMOS**, Escuela de Biología de la Universidad Autónoma de Puebla, Puebla, Puebla, 72570 México, **EDMUNDO PÉREZ-RAMOS**, Museo de Zoología, Facultad de Ciencias Universidad Nacional Autónoma de México, Apartado Postal 70-399, México, Distrito Federal 04510, México, and **JORGE A. VARGAS-CONTRERAS**, Instituto de Ecología

y Alimentos de la Universidad Autónoma de Tamaulipas, Blvd. Adolfo López Mateos No. 928, Ciudad Victoria, Tamaulipas, 87040 México.

EUMECES ANTHRACINUS (Coal Skink). USA: TENNESSEE: HENDERSON CO: 0.6 km N Jones Road off Rt. 22A (35°36.39'N, 88°25.79'W). 9 April 1998. B. P. Butterfield, J. Hobbs, and B. Britt. Austin Peay State University Museum of Zoology (APSU 5991). Verified by Floyd Scott. New county record (Redmond et al. 1990, Annotated Checklist and Bibliography of Amphibians and Reptiles of Tennessee [1835 through 1989]. Austin Peay St. Univ. Center for Field Biol. Misc. Publ. 4:1–173). A second individual was collected at the same site on 4 May 1998 (APSU 5992). Fewer than ten individuals have previously been reported from Tennessee (Redmond et al., *op. cit.*).

Submitted by **BRIAN P. BUTTERFIELD, JEREMY HOBBS,** and **BRYAN BRITT**, Department of Biology, Freed-Hardeman University, Henderson, Tennessee 38340-2399, USA.

EUMECES TETRAGRAMMUS BREVILINEATUS (Short-lined Skink). USA: TEXAS: HUDSPETH CO: near Squaw Spring at the University of Texas at El Paso Indio Mountains Research Station (30°48.03'N, 105°00.82'W), 1268 m elev. 13 June 1998. G. Walker Johnson. UTEP 17707. Verified by Carl S. Lieb. New county record; extends range of the subspecies ca. 26 airline miles NE of C. E. Miller Ranch, 11 mi W Valentine, Presidio County, Texas (Lieb 1985, Contr. Sci. Nat. Hist. Mus. Los Angeles Co. 357:1–19). Squaw Spring is located in a rocky canyon containing Chihuahuan Desert scrub vegetation.

Submitted by **G. WALKER JOHNSON** and **JERRY D. JOHNSON**, Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998, USA.

GYMNOPHTHALMUS UNDERWOODI. ANTIGUA: PARISH OF SAINT JOHN: 1.3 km W Cedar Grove. 21 August 1998. R. Powell. Bobby Witcher Memorial Collection, Avila College (BWMC 06239). Verified by S. Blair Hedges. Specimen represents the first record for the island and the northernmost record for the species (Schwartz and Henderson 1991, Amphibians and Reptiles of the West Indies: Descriptions, Distributions, and Natural History. Univ. Florida Press, Gainesville. 720 pp.). This parthenogenetic lizard is an effective colonizer with a distribution ranging from northern South America (Guyana and Suriname) through Trinidad and Tobago and into the Lesser Antilles (Barbados, St. Vincent, Guadeloupe, and now Antigua).

Submitted by **ROBERT POWELL**, Department of Natural Sciences, Avila College, Kansas City, Missouri 64145-1698, USA (e-mail: powellr@mail.avila.edu), and **KEVEL LINDSAY**, Island Resources Foundation, P.O. Box 103, St. John's, Antigua (e-mail: klindsay@irf.org).

HEMIDACTYLUS GARNOTII (Indo-Pacific Gecko). USA: FLORIDA: VOLUSIA CO: 2226 Magnolia Drive, South Daytona. 26 November 1998. Anthony T. Reppas. Florida Museum of Natural History, University of Florida (UF 116050). Verified by David L. Auth. New County Record; gravid female found at 2200 h on window pane in residential neighborhood. This introduced species has been observed in 25 counties throughout the Florida pennisula, including Baker County which lies on the Florida/Georgia border.

Submitted by **ANTHONY T. REPPAS**, Department of Interdisciplinary Studies, University of Florida, Gainesville, Florida 32611, USA.

HEMIDACTYLUS MABOUIA (Tropical Gecko). PUERTO RICO: Isla Cueva. 19 January 1977. Collector unknown. Verified by K. de Queiroz. USNM 211432. 25 December 1977. A. Resetar, R. Evers, and M. Evans. FMNH 207302. Verified by A. Resetar. First records for island (Heatwole et al. 1981, Atoll Res. Bull. 251:1–63). La Parguera: Hotel Casablanca. 24 December 1977. A. Resetar, R. Evers, and M. Evans. FMNH 207301. Verified by A. Resetar. Sabana Seca: Caribbean Primate Research Center. 26 December 1977. A. Resetar, R. Evers, and M. Evans. FMNH 207303. Verified by A. Resetar. Historically, in the Puerto Rican region this species was known only from smaller islands, such as Mona, Vieques, Culebra, and the Virgins, while *H. brookii* occurred on the mainland of Puerto Rico (Grant 1932, J. Dept. Agric. Puerto Rico 15:51–57; Kluge 1969, Misc. Pub. Mus. Zool. Univ. Michigan 138:1–78). Garcia Diaz (1967, Stahlia 10:1–6) first reported *H. mabouia* from Puerto Rico proper at Isabela. The last two records add two widely-spaced mainland localities, from a little west of San Juan and the far southwest of the island.

Submitted by **GREGORY C. MAYER**, Department of Biological Sciences, University of Wisconsin-Parkside, Kenosha, Wisconsin 53141, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: ARKANSAS: CLARK CO: Arkadelphia, vicinity of Caddo and Second Sreets, Sec. 20, T7S, R19W. 7 October 1998. Greg White. Henderson State University collection 513–518. Verified by Stan Trauth. About 30 individuals seen on wall of building, 8 collected. Population has been observed for several years. Second record for Arkansas (Paulissen and Buchanan 1990, Herpetol. Rev. 21:22).

Submitted by **GREG WHITE** and **RENN TUMLISON**, Department of Biology, Henderson State University, Arkadelphia, Arkansas 71999, USA.

LIOLAEMUS GRACILIS. ARGENTINA: SAN LUIS. JUNÍN DEPARTMENT: Ruta Nacional No. 20, Km 250, 4 km S Paraje La Unión (32°11'S, 65°40'W). 3 March 1999. M. Morando, L. J. Avila, and L. Belver. Herpetological collection, Fundación Miguel Lillo, Tucumán, Argentina (FML 8190). Verified by F. Lobo. First record for province of San Luis and easternmost record for the species in central Argentina; nearest record for this species is in Mendoza province near Mendoza-San Luis border, Desaguadero River edge, ca. 160 km W (airline) (Cei 1986, Mon. IV Mus.reg. Sci. Nat. Torino. 527 pp.).

Submitted by **MARIANA MORANDO** and **LUCIANO JAVIER AVILA**, CRILAR-CONICET, Mendoza y Entre Ríos s/n, C. P. 5301, Anillaco, La Rioja, Argentina.

OPHISAURUS ATTENUATUS ATTENUATUS (Western Slender Glass Lizard). USA: OKLAHOMA: LOGAN CO: 0.7 km S and 4.3 km E Marshall. R. Lardie. 26 May 1991. Female, DOR from an unsurfaced road in bottomland forest. St. Vincent's University, Shawnee, Oklahoma collection (SGU 306). Verified by Jeffrey T. Burkhart. First record for county and fills gap in distribution.

Submitted by **RICHARD L. LARDIE**, 313 Flintridge Road, Enid, Oklahoma 73703, USA.

SCELOPORUS SCALARIS BROWNORUM (Brown's Bunch Grass Lizard). MÉXICO: NAYARIT: Sierra de Alica, Bajío de las Palas, municipality of La Yesca, 2000 m (21°45'N, 104°24'W). 21 July 1996. Paulino Ponce-Campos. One specimen, female; Facultad de Ciencias Naturales y Agropecuarias, Universidad Autónoma de Guadalajara, México (UAGM R-398). Verified by H. M. Smith. New state record. Previously recorded from Aguascalientes, Durango, Jalisco, and Zacatecas (Smith et al. 1997, Southwest. Nat., 42:290–301).

Submitted by **PAULINO PONCE-CAMPOS** and **SARA M. HUERTA-ORTEGA**, Bosque Tropical, A. C., Apartado Postal 5-515, Guadalajara, Jalisco 45042, México.

SCELOPORUS TORQUATUS MELANOGASTER (Blackbelly Crevice Swift Lizard). MÉXICO: NAYARIT: Sierra del Pinabete, municipality of El Trapiche (21°21'N, 104°14'W). 6 February 1995. Paulino Ponce-Campos. Three specimens photographed. Facultad de Ciencias Naturales y Agropecuarias, Universidad Autónoma de Guadalajara, México (UAGM R-420, one specimen at 2225 m elev.), and two specimens (UAGM R-421a-b at 2165 m elev.). Verified by H. M. Smith. New state record (Olson 1990, Bull. Chicago Herpetol. Soc. 25:117–127).

Submitted by **PAULINO PONCE-CAMPOS** and **SARA M. HUERTA-ORTEGA**, Bosque Tropical, A. C., Apartado Postal 5-515, Guadalajara, Jalisco 45042, México.

SCELOPORUS UNDULATUS SPEARI (Cabeza de Vaca Prairie Lizard). USA: NEW MEXICO: Doña Ana Co: 4.7 km W Sunland Park city hall. 12 May 1996. C. G. Schmitt. MSB 60752; 31 km E Luna County line on Rt. I-10. 15 May 1985. J. Camper field class. TCWC 63639; Anapra Study Plot, 31°47'10"N. 106°35'08"W. 9 October 1970. 8 May 1975. 30 May–1 June 1977. R. G. Worthington. UTEP 561, 2679, 3018; near Aden Crater, ca. 26 km S Las Cruces. 1 September 1974. T. R. Van Devender. UTEP 2557. Grant Co: 8 km W Hachita, Rt. 9. 25 September 1974. T. R. Van Devender. UTEP 2562–3. Luna Co: 1.4 km S Victorio ranch, Rt. 9. 18 May 1978. R. G. Webb et al. UTEP 3536; Cedar Mts., ca. 14.5 km E Hachita. 6 July 1996. D. I. Lannutti et al. UTEP 16403; 22.5 km W on Rt. 27, 5.7 km NW Nutt (32°36'09"N, 107°29'16"W), 1453.6 m elev. 15 July 1977. R. W. Axtell and R. G. Webb. UTEP 17433. Otero Co: ca. 51 km ENE jct Hueco Inn (on Rts. 62/180) & side road into New Mexico (32°07'26"N, 105°36'23"W), 1501.8 m elev. 17 July 1977. R. W. Axtell and R. G. Webb. UTEP 17432. Sierra Co: 0.5 km N Engle. 7 September 1981. G. M. Ferguson, C. S. Lieb, R. G. Webb. UTEP 8955-7. Verified by Richard L. Holland. Extend known range (Smith et al. 1995, Trans. Kansas Acad. Sci. 98:44–60) from north-central Chihuahua ca. 185 km northward into the Jornada del Muerto Basin, and eastward across the southern part of the Tularosa Basin to the southern part of the Salt Basin in New Mexico.

Submitted by **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 90309-0334, USA, **RALPH AXTELL**, Biological Sciences, Southern Illinois University, Edwardsville, Illinois 62025, USA, and **ROBERT G. WEBB**, Biological Sciences, University of Texas at El Paso, El Paso, Texas 79999, USA.

SCELOPORUS UNDULATUS TEDBROWNI (Mescalero Prairie Lizard). USA: TEXAS: Lamb Co: 8.5 km E Whiteface Rest Area, Rt. 114. 17 July 1984. TCWC 62968; Hockley Co: 8.5 km N Sudan, Rt. 303. 17 July 1984. TCWC 62971; Terry Co: Mound Lake. 18 July 1984. TCWC 62965; Yoakum Co: 16.9 km E Plains, Rt. 380. 11 July 1984. TCWC 62964. All collected by D. King and D. Kizirian. Verified by Richard L. Holland. Extends known range (Smith et al. 1992, Bull. Maryland Herpetol. Soc. 28:123–149) from Andrews County, the only county in Texas from which it was previously recorded, about 190 km northward and eastward into extreme western Lamb and Hockley counties. The Cochran and Yoakum county records in Dixon (1987, Amphibians and Reptiles of Texas, Texas A&M Univ. Press, College Station), there referred to *S. u. garmani,* fall likewise into the range of *S. u. tedbrowni,* which recent collections show has a latitudinal range in New Mexico about the same as in Texas, from southern Roosevelt County to southern Lea County.

Submitted by **HOBART M. SMITH** and **DAVID CHISZAR**, Museum of Natural History, University of Colorado, Boulder, Colorado 80309, USA.

SPHAERODACTYLUS NICHOLSI (Nichols' Least Gecko). PUERTO RICO: Isla Guayacan. 25 December 1977. A. Resetar, R. Evers, and M. Evans. FMNH 207306. Verified by A. Resetar. Isla Cueva. 25 December 1977. A. Resetar, R. Evers, and M. Evans. FMNH 207307–8. Verified by A. Resetar. First records for both islands (Heatwole et al. 1981, Atoll Res. Bull. 251:1–63).

Submitted by **GREGORY C. MAYER**, Department of Biological Sciences, University of Wisconsin-Parkside, Kenosha, Wisconsin 53141, USA.

SPHAERODACTYLUS ROOSEVELTI (Roosevelt's Least Gecko). PUERTO RICO: Isla Cueva. 25 December 1977. A. Resetar, R. Evers, and M. Evans. FMNH 207305. Verified by A. Resetar. First record for island (Heatwole et al. 1981, Atoll Res. Bull. 251:1–63).

Submitted by **GREGORY C. MAYER**, Department of Biological Sciences, University of Wisconsin-Parkside, Kenosha, Wisconsin 53141, USA.

SPHENOMORPHUS ASSATUS (Red Forest Skink). HONDURAS: Santa Lucía (13°55.17'N, 88°23.43'W), 370 m elev. 23 October 1998. E. Köhler, G. Köhler, and J. R. McCranie. Verified by L. D. Wilson. SMF 78933. First record for country; extends range ca. 75 airline km ESE of Hacienda El Morito, Departamento de Chalatenango, El Salvador (Mertens 1952, Abh. senckenb. naturf. Ges. 487:1–120).

Submitted by **JAMES R. McCRANIE**, 10770 SW 164th Street, Miami, Florida 33157-2933, USA, and **GUNTHER KÖHLER**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt, Germany.

STENOCERCUS PECTINATUS. ARGENTINA: SANTA FE: San Martín Department: El Trébol (32°20'S, 61°37'W). Pasquali and Trucchio. CENAI 359. 9 de Julio Department: Gregoria Perez de Denis (Estación El Nochero) (28°14'S, 61°32'W). CENAI 360, Escuela 842. Verified by G. R. Carrizo. CENAI collection (ex Centro Nacional de Investigaciones Iológicas) is now housed in Museo Argentino de Ciencias Naturales Bernardino Rivadavia. First records for the province, northeasternmost record for the species in Argentina and extends the known distribution 420 km (airline) NE from previous and northernmost vouchered citation (Genise 1985, Boletín Asoc. Herp. Argentina 1[1–3]:18). Formerly published records for Mendoza, Santa Cruz, and Chubut provinces are very doubtful and not confirmed by vouchers. Records for Santiago del Estero and Tucumán, published by Cei (1986, Reptiles del Centro, Centro-oeste y Sur de la Argentina. Mon. IV. 527 pp., and 1993, Reptiles del Noroeste, Nordeste y Este de la Argentina, Mon. XIV, 949 pp.) are not included in the last regional lists (Gallardo et al. 1985, Hist. Nat. 5[13]:97–103; Lavilla et al. 1993, Claves para la identificación de los anfibios y reptiles de la provincia de Tucumán (Argentina). Misc. 95. Fund. M. Lillo. 30 pp.). Reported distribution by Cei (1986, 1993, *op. cit.*) for Brazil and Uruguay may have resulted from confusion of this taxon with *Stenocercus azureus*, because no citations were given for *S. pectinatus* in these countries. Voucher records restrict the distribution to La Pampa, San Luis, Córdoba, Río Negro, Buenos Aires, and Santa Fe provinces.

Submitted by **LUCIANO JAVIER AVILA**, CRILAR-CONICET, Mendoza y Entre Ríos s/n, C.P. 5301, Anillaco, La Rioja, Argentina.

XANTUSIA VIGILIS VIGILIS (Desert Night Lizard). USA: CALIFORNIA: Inyo Co: 13 km W Bishop; Starlite Drive (37°20'N, 118°32'W), 1780 m elev. 25 May 1997. Richard Scott. Verified by Kent Beaman. LACM 145078. Extends range along E slope of the Sierra Nevada 90 km N from previous record near Lone Pine (LACM 121550; plotted in Bezy 1982, Cat. Amer. Amph. Rept. 302.1) and W across the Owens Valley from the Inyo-White Mountains (Macey 1986, *In* C. A. Hall, Jr. and D. J. Young [eds.], Natural History of the White-Inyo Range, Eastern California and Western Nevada and High Altitude Physiology. Univ. California White Mountain Res. Station Symposium 1, pp. 119–128; Papenfuss 1986, *ibid*, pp. 129–136). Vegetation at the site consists of sagebrush (*Artemisia tridentata*) and blackbrush (*Coleogyne ramosissima*); as with other records from this part of the range of *X. vigilis*, the specimen was found under rocks rather than yucca.

Submitted by **RICHARD R. SCOTT**, 8800 Starlite Drive, Bishop, California 93514, USA, **ROBERT L. BEZY**, Herpetology, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA, and **NORMAN J. SCOTT, JR.**, U.S. Geological Survey, Piedras Blancas Research Station, P.O. Box 70, San Simeon, California 93452, USA.

SERPENTES

AGKISTRODON CONTORTRIX LATICINCTUS (Broad-banded Copperhead). USA: OKLAHOMA: Logan Co: 0.75 km S and 8.3 km E Marshall. Female collected at 1107 hrs under a red sandstone rock in a roadside ditch near a gully in oak woods. 9 June 1991. R. Lardie. St. Vincent's University, Shawnee, Oklahoma collection (SGU 637). Verified by Jeffrey T. Burkhart. First record for county on northwestern edge of Oklahoma range (Conant and Collins 1998, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third edition expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.). Specimen was maintained alive until November 1996.

Submitted by **RICHARD L. LARDIE**, 313 Flintridge Road, Enid, Oklahoma 73703, USA.

AGKISTRODON CONTORTRIX MOKASEN (Northern Copperhead). USA: KENTUCKY: Owen Co: Eagle Creek Campground. 28 September 1996. M. Bramlage. Thomas More College (TMC R1). Verified by Melissa Obermeyer. New county record. Known previously only from an anecdotal account in Funkhouser (1925, Wild Life in Kentucky, Kentucky Geol. Surv., Frankfort. 385 pp.) (see also Meade 1993, Ph.D. Dissertation, University of Southern Mississippi. 608 pp.).

Submitted by **JOHN W. FERNER, MICHAEL BRAMLAGE**, and **WILLIAM S. BRYANT**, Department of Biology, Thomas More College, Crestview Hills, Kentucky 41017, USA.

ARRHYTON EXIGUUM EXIGUUM (Virgin Islands Racer). BRITISH VIRGIN ISLANDS: ANEGADA: on road between The Settlement and Loblolly Bay, ca. 0.5 km N The Settlement. Collected and photographed 24 April 1998. Todd Campbell (UF 115972A–B). New record for Anegada (Schwartz and Henderson 1991, Amphibians and Reptiles of the West Indies, Univ. Florida Press, Gainesville. 720 pp.; Richard Thomas, pers. comm.).

Submitted by **TODD CAMPBELL**, Department of Ecology and Evolutionary Biology, 569 Dabney Hall, University of Tennessee, Knoxville, Tennessee 37996, USA (e-mail: lizardman@utk.edu), USA, and **KYM ROUSE CAMPBELL**, The Cadmus Group, 136 Mitchell Road, Oak Ridge, Tennessee 37830, USA.

BOTHRIECHIS SCHLEGELII (Eyelash Palm-pitviper). HONDURAS: Departamento de Gracias a Dios: Mocorón. 13 June 1997. C. J. Franklin and J. Franklin. UTA Color Slide # 22642. Verified by J. A. Campbell. New departmental record (Wilson and Meyer 1985. The Snakes of Honduras. Milwaukee Public Museum).

Submitted by **CARL J. FRANKLIN**, Dallas Zoo Department of Herpetology, 650 South R.L. Thornton Fwy (I-35), Dallas, Texas 75203, USA (e-mail: HERPKING@ix.netcom.com) and **JACQUELINE FRANKLIN**, Louise Wolf Kahn Elementary School, 610 Franklin Avenue, Dallas, Texas 75211, USA.

CARPHOPHIS AMOENUS HELENAE (Midwest Worm Snake). USA: KENTUCKY: Campbell Co: Grants Lick, below Fairlane Drive on S-facing slope, 0.5 km N Licking River (38°48.750'N, 84°23.039'W). 17 May 1998. P. J. Krusling and J. W. Ferner. Cincinnati Museum of Natural History (CMNH 5731). Verified by J. G. Davis. New county and regional northern Kentucky record (Meade 1993, Ph.D. Dissertation, University of Southern Mississippi. 608 pp.).

Submitted by **PAUL J. KRUSLING**, Geier Collections and Research Center, Museum of Natural History and Science, Cincinnati Museum Center, 1720 Gilbert Avenue, Cincinnati, Ohio 45202, USA, and **JOHN W. FERNER**, Department of Biology, Thomas More College, Crestview Hills, Kentucky 41017, USA.

CROTALUS HORRIDUS (Timber Rattlesnake). USA: OKLAHOMA: Garfield Co: 11 km S and 2.1 km E Covington. Small female collected at 2235 h near Crowsnest Creek in bottomland forest. 14 May 1984. R. Lardie. Maintained alive until November 1996. St. Gregory's University, Shawnee, Oklahoma Collection (SGU 636); complete dried skin of a *C. horridus* from 11.2 km S and 4.5 km E Covington, collected from a concrete dam of a small lake on 4-D Creek. Spring 1983. SGU 601. Both specimens verified by Jeffrey T. Burkhart. These are voucher specimens for the county on the extreme northwestern edge of the range of *C. horridus* (Conant and Collins 1998. Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third edition expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.). A specimen reported earlier from 11 km SE Covington (Lardie 1979, Herpetol. Rev. 10:24–25) in the private collection of Cline Hereford Farm, no longer exists.

Submitted by **RICHARD L. LARDIE**, 313 Flintridge Road, Enid, Oklahoma 73703, USA.

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake). USA: COLORADO: El Paso Co: Edison. 17 April 1993. H. M. Smith. UCM 56796. Verified by Richard L. Holland. First county record (Hammerson 1986, Amphibians and Reptiles on Colorado. Publ. Colorado Div. Wildlife. 131 pp.); at the western known edge of the range of the species on southeastern Colorado, more or less on a line with the records for Pueblo County (Hammerson, *op. cit.*) and Elbert County (Chiszar et al. 1992, Bull. Chicago Herpetol. Soc. 27:165). A partial shed skin about 1200 mm in length, lacking the tail, head and several inches of the neck (as evident from the scale row counts). The snake would be of record or near record maximum size, presumably even larger than the one that left the skin in Elbert County (Chiszar et al., *op. cit.*).

Submitted by **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0315, USA.

ELAPHE OBSOLETA LINDHEIMERII (Texas Rat Snake). USA: OKLAHOMA: Dewey Co: 6.5 km E and 8.1 km N Canton (in Blaine County). 3 May 1992. R. Lardie. St. Gregory's University, Shawnee, Oklahoma (SGU 326); Major Co: Williams Scout Reservation. 3.3 km E and 6.5 km S Cleo Springs. 12 June 1989. D. Crosswhite and J. Stewert. SGU 168; 15.2 km S Waynoka, 7 km E Bouse Junction on U.S. Rt. 412. 18 May 1996. Gary Lardie. SGU 674; 9 km N Ames. 24 July 1994. R. Lardie. SGU 604; 4.5 km W Ames. 24 July 1994. R. Lardie. SGU 605; Alfalfa Co: 12.7 km E Byron. 29 May 1995. R. Lardie and George Lardie. SGU 703; Grant Co: 10 km S and 4.3 km W Manchester. 6 June 1981. R. Lardie. Oklahoma Baptist University, Shawnee, Oklahoma (OBU 1938); 13 km N Nash on S-132. 5 September 1976. R. Lardie. OBU 1559; Kingfisher Co: 10.3 km W and 0.3 km S Lacey. 5 April 1981. R. Lardie. OBU 1832; Garfield Co: 1.3 km S and 5.4 km E Carrier. 25 July 1995. R. Lardie. SGU 479; Fairgrounds, north Enid. 17 October 1996. A. Lardie. SGU 628; 5.4 km N Imo. 17 June 1995. R. Lardie. SGU 484; 7 km N and 0.6 km E Imo. 13 June 1977. R. Lardie. SGU 477; 1.2 km S and 3.6 km E Carrier on S-45. 18 May 1996. R. Lardie. SGU 552; 3.8 km N and 1.6 km W Waukomis. 17 May 1996. R. Lardie. SGU 550; Douglas. 17 May 1992. R. Lardie. SGU 292; Breckenridge. Summer 1991. M. Meier. SGU 702. All SGU specimens were verified by Jeffrey T. Burkhart. All OBU specimens were verified by Jeffrey H. Black. These 18 specimens exhibit many color and pattern characteristics of *E. o. lindheimerii*, described in Conant and Collins (1998, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third edition expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.). These include distinct dorsal blotches, usually set in reddish color, a series of smaller lateral blotches on each side, frequently connected by a stripe 3–3.5 scale rows wide, yellow-gray to yellow background color and a gray to black head. One specimen from southeastern Garfield County (SGU 646) and most observed from Williams Scout Reservation in Major County were typical of *E. o. obsoleta*. All specimens reported here are considered intergrades between the two subspecies. SGU 326 is the first verified record of *E. obsoleta* for Dewey County. These records further corroborate the predicted distribution published by Conant and Collins (1998, *op. cit.*) for *E. o. obsoleta* x *lindheimerii* in western Oklahoma.

Submitted by **RICHARD L. LARDIE**, 313 Flintridge Road, Enid, Oklahoma 73703, USA, **DOYLE L. CROSSWHITE**, Division of Science, St. Gregory's University, 1900 West MacArthur Drive, Shawnee, Oklahoma 74801, USA, and **MARTIN K. MEIER**, 1529 Smith Circle, Wichita, Kansas 67201, USA.

ELAPHE SITULA (Leopard Snake). CROATIA: Sipan Island, ca. 20 airline km NW Dubrovnic. 14 September 1954. M. Radovanovic. Hungarian Natural History Museum (HNHM 65.137.1). Verified by B. Buzas. First island record; previously documented for nearby islands of Mljet and Korcula (Obst et al. 1993, pp. 431–453 *In* W. Bohme [ed.] Handbuch der Reptilien und Amphibien Europas, Vol. 3/I, Schlangen [Serpentes], I. Aula, Wiesbaden; K. Schulz 1996, A Monograph of the Colubrid Snakes of the Genus Elaphe Fitzinger. Koeltz, Havlickuv Brod. 439 pp.). Corbett (1989, Conservation of European Reptiles and Amphibians. Helm, London. 274 pp.) stated that this species is in rapid decline throughout its range. It is thus probable that this snake has since become extinct on Sipan.

Submitted by **BÁLAZS FARKAS**, Department of Zoology, Hungarian Natural History Museum, Pf. 137, H-1431 Budapest, Hungary, and **TAMÁS TÓTH**, Budaorsi ut 92/b, H-1118 Budapest, Hungary.

GYALOPION CANUM (Western Hooknose Snake). MÉXICO: MICHOACAN: Cerro El Obispo, 3 km south of Carapan, 2100 m (19°49'N, 102°03'W). 15 November 1991. Paulino Ponce-Campos. Facultad de Ciencias Naturales y Agropecuarias, Universidad Autónoma de Guadalajara, México (UAGM R-246). Verified by H. M. Smith. New state record. Previously recorded from Chihuahua, Coahuila, Durango, Nuevo León, San Luis Potosí, Sonora, and Zacatecas. (Hardy 1976, Cat. American Amph. Rept. 182.1–182.4).

Submitted by **PAULINO PONCE-CAMPOS** and **SARA M. HUERTA-ORTEGA**, Bosque Tropical, A. C., Apartado Postal 5-515, Guadalajara, Jalisco 45042, México.

HETERODON PLATIRHINOS (Eastern Hognose Snake). USA: KENTUCKY: Boone Co: Rt. 20 just S Petersburg, DOR (39°02.430'N, 84°52.180'W). 13 July 1997. J. W. Ferner and P. J. Krusling. Cincinnati Museum of Natural History (CMNH 5749). Verified by Melissa Obermeyer. New voucher specimen for county record; previous vouchers from Baker Hunt Foundation of Covington, Kentucky have been lost (Meade 1993, Doctoral Dissertation, University of Southern Mississippi. 608 pp.).

Submitted by **JOHN W. FERNER**, Department of Biology, Thomas More College, Crestview Hills, Kentucky 41017, USA, and **PAUL J. KRUSLING**, Geier Collections and Research Center, Museum of Natural History and Science, Cincinnati Museum Center, 1720 Gilbert Avenue, Cincinnati, Ohio 45202, USA.

LAMPROPELTIS TRIANGULUM DIXONI (Dixon's Milk Snake). MEXICO: GUANAJUATO: "Guanajuato." 1875. Alfredo Dugés. MHNL (Mus. Hist. Nat. Lyon) 42000709. Verified by Richard L. Holland. First record for state, extending known range of subspecies about 160 km SW of vicinity of Rio Verde, San Luis Potosí (Williams 1988, Systematics and Natural History of the American Milk Snake, *Lampropeltis triangulum*. 2nd ed. Publ. Milwaukee Pub. Mus. 176 pp.), assuming, as is highly likely, that the specimen was taken in the vicinity of Ciudad Guanajuato. It is a logical extension into an area from which no other records of the species are available, and north of the range of *L. t. nelsoni* in the southern part of the state.

Submitted by **HOBART M. SMITH** and **DAVID CHISZAR**, University of Colorado Museum, Boulder, Colorado 80309-0315, USA, and **JOËL CLARY** and **JEAN-LOUIS MARTELLI**, Muséum d'Histoire Naturelle, 28 Boulevard des Belges, 69006 Lyon, France.

LEPTOTYPHLOPS DULCIS DULCIS (Texas Blind Snake). USA: OKLAHOMA: Johnson Co: 1.6 km E and 1.6 km N Ponotoc, under a limestone rock in an open rocky area. 31 May 1995. St. Gregory's University, Shawnee, Oklahoma collection (SGU 700). Verified by Jeffrey T. Burkhart. County record at eastern edge of range where Webb (1970, Reptiles of Oklahoma, Univ. Oklahoma Press, Norman. 370 pp.) considered *L. dulcis* to be intergrades of *dulcis* x *dissectus*. This specimen has one supralabial on each side (*L. d. dulcis*) instead of two supralabials (*L. d. dissectus*).

Submitted by **RICHARD L. LARDIE**, 313 Flintridge Road, Enid, Oklahoma 73703, USA, **DOYLE L. CROSSWHITE**, Division of Sciences, St. Gregory's University, 1900 West MacArthur Drive, Shawnee, Oklahoma 74801, USA, and **JEFFREY T. BURKHART**, Division of Sciences, Paradise Valley Community College, Phoenix, Arizona 85032, USA.

LIOPHIS ALMADENSIS (Jararaquinha do Campo). BRAZIL: MARANHÃO: Municipality of Balsas (07°31'40"S, 52°02'31"W). 19 May 1987. Museu Paraense Emílio Goeldi (MPEG 19323). Veri-

fied by T. de Lema. Young male. According to Dixon (1989, Smithson. Herpetol. Inform. Ser. 79:1–28), this species is know from all plant formations in Brazil except Caatinga and Amazon rainforest. The municipality of Balsas is located in a Caatinga region and this specimen is the first record for the state of Maranhão.

Submitted by **NELSON RUFINO**, Linha de Pesquisa em Herpetologia, Pontifícia Universidade Católica do Rio Grande do Sul, Avenida Ipiranga, s/n. CEP: 90619-900, Porto Alegre, Brazil.

MASTICOPHIS MENTOVARIUS (Neotropical Coachwhip). HONDURAS: DEPARTAMENTO DE GRACIAS A DIOS: Mocorón. 12 June 1997. C. J. Franklin and J. Franklin. UTA-R42649. Verified by J. A. Campbell. New departmental record (Wilson and Meyer 1985. The Snakes of Honduras. Milwaukee Public Museum).

Submitted by **CARL J. FRANKLIN**, Dallas Zoo Department of Herpetology, 650 South R.L. Thornton Fwy (I-35), Dallas, Texas 75203, USA (e-mail: HERPKING@ix.netcom.com) and **JACQUELINE FRANKLIN**, Louise Wolf Kahn Elementary School, 610 Franklin Avenue, Dallas, Texas 75211, USA.

NERODIA ERYTHROGASTER TRANSVERSA (Blotched Water Snake). USA: TEXAS: ARKANSAS CO: Arkansas National Wildlife Refuge. 14 April 1985. A. Chaney and party. TAIC 5504. Verified by Steve A. Smith. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **MICHAEL JAMES McCOID**, Department of Biology, Campus Box 158, Texas A&M University, Kingsville, Texas 78363, USA.

OXYRHOPUS RHOMBIFER BACHMANNI. ARGENTINA: RIO NEGRO: DEPARTAMENTO GENERAL ROCA: on Ruta Provincial N° 6 (38°32'S, 67°33'W), 59 km N General Roca. 12 March 1999. L. J. Avila and M. Morando. Verified by G. Scrocchi. Herpetological collection, Fundación Miguel Lillo, Tucumán, Argentina (FML 8191). First record for Rio Negro province and southernmost record for the species (Cei 1986, Mon. IV Mus. reg. Sci. Nat. Torino. 527 pp.). Nearest record for taxon is Lihué Calel, Departmento Lihué Calel, La Pampa Province, ca. 175 km airline NE (Tiranti and Avila 1997, Bull. Maryland Herpetol. Soc. 33[3]:97–117).

Submitted by **LUCIANO JAVIER AVILA** and **MARIANA MORANDO**, CRILAR-CONICET, Mendoza y Entre Ríos s/n, C. P. 5301, Anillaco, La Rioja, Argentina.

PSUESTES POECILONOTUS (Bird-eating Tree Snake). HONDURAS: DEPARTAMENTO DE GRACIAS A DIOS: ca. 30 km south of Mocorón. 10 June 1997. C. J. Franklin and J. Franklin. UTA-R42655. Verified by J. A. Campbell. New departmental record (Wilson and Meyer 1985. The Snakes of Honduras. Milwaukee Public Museum).

Submitted by **CARL J. FRANKLIN**, Dallas Zoo Department of Herpetology, 650 South R.L. Thornton Fwy (I-35), Dallas, Texas 75203, USA (e-mail: HERPKING@ix.netcom.com) and **JACQUELINE FRANKLIN**, Louise Wolf Kahn Elementary School, 610 Franklin Avenue, Dallas, Texas 75211, USA.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). MÉXICO: NUEVO LEON: metropolitan area of Monterrey. 1990–97. Manuel Nevárez de los Reyes. Universidad Autónoma de Nuevo León Herpetological Collection (UANL 5248–53). Verified by Arturo Contreras Arquieta. Records confirm the establishment of the species in the state, previously recorded for Colonia Ancira at Monterrey (Alvarez and Murillo 1996, Vert. Mex. 2:1–2).

Submitted by **MANUEL NEVÁREZ**, Laboratorio de Herpetología, Facultad de Ciencias Biológicas, Universidad Autónoma de Nuevo León, Apartado Postal 513, San Nicolás de los Garza, Nuevo León, México, C.P. 66450.

SENTICOLIS TRIASPIS (Green Rat Snake). USA: ARIZONA: PIMA CO: Baboquivari Mountains, Thomas Canyon, ca. 1460 m elev. (NE quadrant SW quadrant Sec. 24, R7E, T19S). 27 September 1998. D. Emmons. ASU living specimen (KU Color Slide 11610). Male (785+242 mm, 128 g) captured crawling among oak leaf litter at 1645 h. First documented specimen from the main massif of the Baboquivari Mountains (Price 1991, Cat. Amer. Amphib. Rept. 491:1–3). Substantiates sight records from Brown Canyon. Previous specimens reported from this range (e.g., Fowlie 1965, Snakes of Arizona. Azul Quinta Press, Fallbrook, California. xxiii + 164 pp.; Stebbins 1985, Peterson Field Guide to Western Reptiles and Amphibians. Houghton Mifflin, Boston, Massachusetts. 336 pp.) are apparently from the adjoining Quinlan Mountains (Kitt Peak).

Submitted by **ANDY HOLYCROSS**, Biology Department, Arizona State University, Tempe, Arizona 85287-1501, USA.

STORERIA DEKAYI (Brown Snake). USA: KANSAS: STAFFORD CO: Quivira National Wildlife Refuge, 0.25 km E of western refuge boundary, Richardson Tract (SW 1/4 of SE 1/4 of Sec. 20, T21S, R11W), ca. 527 m elev. 14 Nov 1998. G. H. Farley. KU 288629. Verified by Joseph T. Collins. First record for county; confirms presence in this portion of the Lower Arkansas River Basin. One of seven similar-sized individuals observed within 0.75 km of the collection locality on the same date. DOR; collected under Kansas Special Use Permit 98012.

Submitted by **GREG H. FARLEY**, Department of Biological Sciences and Sternberg Museum of Natural History, Fort Hays State University, Hays, Kansas 67601, USA.

TANTILLA NIGRICEPS FUMICEPS (Texas Black-headed Snake). MÉXICO: NUEVO LEON: Fraccionamiento del Lago, San Nicolás de los Garza. 9 September 1993. Manuel Nevárez de los Reyes. Universidad Autónoma de Nuevo León Herpetological Collection (UANL 5241). Verified by James R. Dixon. Fourth record for Mexico and second for the state; extends range ca. 90 km W of the previous record at Rancho el 86 in Cerralvo (Liner et al. 1978, Herpetol. Rev. 9:22).

Submitted by **MANUEL NEVÁREZ**, Laboratorio de Herpetología, Facultad de Ciencias Biológicas, Universidad Autónoma de Nuevo León, Apartado Postal 513, San Nicolás de los Garza, Nuevo León, México, C.P. 66450.

TRIMORPHODON TAU TAU (Mexican Lyre Snake). MÉXICO: NUEVO LEON: Cerro de la Silla at Monterrey. July 1991. Collector unidentified. Universidad Autónoma de Nuevo León Herpetological Collection (UANL 5243). Verified by David Lazcano Villarreal. Third record for state; species was recorded at the same locality (Martin del Campo R. 1953, Contribución al Conocimiento de la Herpetologia de Nuevo Leon. Universidad) and from Iturbide (Blody et al. 1987, Herpetol. Rev. 18:21).

Submitted by **MANUEL NEVÁREZ**, Laboratorio de Herpetología, Facultad de Ciencias Biológicas, Universidad Autónoma de Nuevo León, Apartado Postal 513, San Nicolás de los Garza, Nuevo León, México, C.P. 66450.

Additional New Regional and Local Records of Amphibians and Reptiles from the State of Falcón, Venezuela

ABRAHAM MIJARES-URRUTIA
and
ALEXIS ARENDS R.
Centro de Investigaciones en Ecología y Zonas Áridas (CIEZA)
Universidad Francisco de Miranda, Apartado 7506
Coro 4101-A, Venezuela
e-mail (AM): amijares@funflc.org.ve
e-mail (AA): aarends@reacciun.conicit.ve

The herpetological survey of the state of Falcón developed by CIEZA personnel has resulted in several new species records for the region (Mijares-Urrutia and Arends 1993). We take this opportunity to report additional records and extensions of distributional ranges of other species of amphibians and reptiles already recorded within the state of Falcón. Specimens reported herein are deposited in the following Venezuelan museums: Colección Herpetológica Regional del Centro de Investigaciones en Ecología y Zonas Aridas, Universidad Francisco de Miranda, Coro (CIEZAH); Museo de Ciencias Naturales de Caracas, Caracas (MCNC); Estación Biológica de Rancho Grande, Ministerio del Ambiente y de los Recursos Naturales Renovables, Maracay (EBRG); Museo de Biología de la Universidad del Zulia, Maracaibo (MBLUZ).

ANURA

Hyla pugnax. VENEZUELA: FALCÓN: Municipio Miranda, La Florida, ± 45.0 km (by road) west of Coro (± 11°14'N, 70°04'W). Collected by A. Mijares-Urrutia, F. Sánchez, and D. Paaton. Verified by J. Aranguren. CIEZAH 401. First record from the state of Falcón and second record from Venezuela (La Marca 1996).

Scinax x-signata. VENEZUELA: FALCÓN: Municipio Colina, La Barranca, 53.6 km (by road) from Coro road to Pueblo Nuevo de la Sierra, ± 310 m (± 11°13'N, 69°27'W). Collected by A. Mijares-Urrutia. Verified by J. Aranguren. CIEZAH 399. First report from the state of Falcón and northwesternmost record of the species in Venezuela (La Marca 1992).

LACERTILIA

Anadia steyeri. VENEZUELA: FALCÓN: Municipio Petit, Cataratas de Hueque, Sierra de San Luis, about 600 m (± 11°11'N, 69°32'W). Collected by T. Barros. Verified by J. E. García. MBLUZ-R 282. Second record from the state of Falcón, and 42.8 km. Northwesternmost record of the species in Falcón (Oftedal 1974; Shreve 1947).

Bachia heteropa lineata. VENEZUELA: FALCÓN: Municipio Colina, Cueva de Chipare, 6.5 km (by road) from Guaibacoa road to Chipare, about 325 m (± 11°25'N, 69°26'W). Collected by A. Mijares and A. Arends. Verified by J. Aranguren. CIEZAH 398. Second record from the state of Falcón and extend in 114.2 km westernmost record of the subspecies (Dixon 1973).

SERPENTES

Liophis reginae zweifeli (Reinita): VENEZUELA: FALCÓN: Municipio Bolívar, Cerro El Danto, Sabanas de Paraguariba, 9.0 km (by road) NE of La Tabla, Sierra de San Luis, about 1350 m (± 11°10'N, 69°42'W). Collected by A. Mijares-Urrutia and D. Daal. Verified by J. Aranguren. CIEZAH 397. First record from the state of Falcón and westernmost record of the species (Dixon 1983; Roze 1966).

Xenodon severus (Sapa): VENEZUELA: FALCÓN: Municipio Colina, near Barrancas, Hueque Dam, Sierra de San Luis, ± 245 m (± 11°14'N, 69°27'W). Collected by J.-M. Hero, F. Sánchez and M. Lampo. Verified by Wolfgang Wüster. CIEZAH 303. First record from the state of Falcón and westernmost record of the species (Lancini and Kornacker 1989; Roze 1966).

Acknowledgments.—We thank those who gave us access to museum specimens and/or catalogues, in particular Francisco Bisbal and Ramón Rivero (EBRG), and Pedro Delgado and Luis Fernando Navarrete (MCNC). Also, our thanks to those who kindly helped corroborate the identity of these specimens. Partial finantial support was provided by grant N° S1-9112-030 from Fundacite-Falcón.

New Lizard Records for La Rioja and Catamarca Provinces, Northwestern Argentina

LUCIANO J. AVILA
and
FERNANDO LOBO
CRILAR-CONICET, Mendoza y Entre Ríos s/n
C.P. 5301, Anillaco, La Rioja, Argentina
e-mail: (LJA) lavila@crilar.com.ar
e-mail: (FL) flobo@crilar.com.ar

Cei (1993) summarized the geographic distribution of lizards in northwestern Argentina, and Etheridge (1993) and Etheridge and Espinoza (1997) added some additional data about *Liolaemus* and *Pristidactylus* species. Recent field work in western Catamarca Province and northern La Rioja Province, and a review of herpetological material housed at the herpetological collection of the Fundación Miguel Lillo, has revealed new records for three species

of *Liolaemus*. Field work was carried out during October and November 1998 and voucher specimens have been deposited at Fundación Miguel Lillo (FML), San Miguel de Tucumán, Tucumán, Argentina. Latitude and longitude were determined with a Garmin™ GPS 38 global positioning device, for the species collected by us. Geographic coordinates for localities of specimens in the FML collection were determined with Atlas de la República Argentina (I-Parte Política. Instituto Geográfico Militar. 1972). Species identification were verified by Gustavo Scrocchi.

Liolaemus elongatus

CATAMARCA PROVINCE: Tinogasta Department: 17.8 km W Chaschuil (27°48'S, 68°13'W). 13 November 1998. F. Lobo and L. J. Avila. FML 7706–09. Record constitutes a range extension of ca. 200 km N (airline) for the species, previously reported (unvouchered) from Cordillera de San Guillermo, north San Juan Province (Cei et al. 1983). We found a voucher specimen from the Cordillera de San Guillermo in FML collection (FML 3550). LA RIOJA PROVINCE: General La Madrid Department: Agua Quemada, on road to Laguna Brava, 47 km NW Alto Jagüé (28°39'S, 68°24'W). 14–15 November 1996. O. Pagaburo and J. Bracamonte. FML 2737 (6 specimens). Quebrada del Leoncito, on road to Laguna Brava, NW Alto Jagüé (28°39'S, 68°24'W). January 1993. O. Pagaburo. FML 2965 (4 specimens). These records fill the gap between our new record in Catamarca Province and previous record in San Juan Province; they are the first records of *Liolaemus elongatus* for La Rioja Province.

Liolaemus robertmertensi

CATAMARCA PROVINCE: Pomán Department: Mollecito (27°47'S, 66°12'W). 18 December 1986. O. Pagaburo, T. Noriega, G. Esteban and L. Claps. FML 1847 (9 specimens). Mollecito (27°47'S, 66°12'W). 16–26 October 1983. O. Pagaburo and E. Terán. FML 1488 (14 specimens). Southernmost extreme of Bolsón del Pipanaco, 3 km S Salar de Pipanaco, SW Mollecitos (27°47'S, 66°12'W). 31 October–1 November 1982. O. Pagaburo and E. Terán. FML 1308 (8 specimens). From Puesto Río Blanco to NW Salar de Pipanaco, SW Mollecito (27°47'S, 66°12'W). October 1984. E. Terán, G. Scrocchi and O. Pagaburo. FML 1616 (7 specimens). Puesto Río Blanco. (27°47'S, 66°12'W). 12 June 1985. O. Pagaburo and R. Montero. FML 1706 (5 specimens). NE Salar de Pipanaco, SW Mollecito (27°47'S, 66°12'W). 19 October 1983. E. Terán and O. Pagaburo. FML 1482 (4 specimens). 15 km W Ruta Provincial Nro. 46 between Siján (28°16'S, 66°14'W) and El Pajonal (28°22'S, 66°18'W). 19 October 1983. E. Terán and O. Pagaburo. FML 1478 (3 specimens). Belén Department: Hualfín (27°15'S, 66°50'W). 22 December 1985. L. Budin. FML 1725 (1 specimens). Hualfín (27°15'S, 66°50'W). 20 March–3 April 1986. A. Budin. FML 1753 (3 specimens). Quebrada Los Viscos. Campamento Central Farallón Negro. (2430 m). 16 December 1995. F. Lobo, A. Marcus, J. Montero and R. Montero. FML 3600 (7 specimens). Andalgalá Department: Villa Vil (27°06'S, 66°49'W). 4 November 1982. O. Pagaburo and E. Terán. FML 1312 (1 specimen). Toma del Río Potrero (27°29'S, 66°18'W). 15 November 1997. G. Scrocchi. FML 6785 (1 specimen). Toma del Río Choya. 5 September 1997. E. Lavilla. FML 6599 (1 specimen); 15 November 1997. G. Scrocchi. FML 06784 (1 specimen). Cerro Choya, near Puesto de Soria (27°25'S, 66°21'W) (2080 m). 29 August 1997. G. Scrocchi. FML 6596 (1 specimen). Rio Blanco near confluence of Rio Candado. 2 September 1997. G. Scrocchi. FML 6601 (1 specimen). Toma del Río Andalgalá. 4 September 1997. G. Scrocchi. FML 6598 (1 specimen). 14 November 1997. G. Scrocchi. FML 6782–83 (2 specimens). Puesto Río Blanco (27°24'S, 66°15'W) 17 November 1997. G. Scrocchi. FML 6786–87 (2 specimens); 14 March 1998. G. Scrocchi. FML 7127–28 (2 specimens). Puesto Río Blanco. Proyecto Agua Rica. (27°27'S, 66°16'W). 24–25 May 1997. G. Scrocchi. FML 6403 (2 specimens). TINOGASTA DEPARTMENT: Medanitos (27°31'S, 67°35'W). 5–8 November 1987. O. Pagaburo and J. Bracamonte. FML 2027 (1 specimen). Los Medanitos, Saujil (27°34'S, 67°37'W) 9–11 November 1991. O. Pagaburo and J. Bracamonte. FML 2699 (1 specimen). Rocky valley 2 km N Termas de Fiambalá (near a old mine campament) (27°43'S, 67°32'W). 12 November 1998. F. Lobo and L. Avila. FML 7710 (1 specimen). Tinogasta (28°04'S, 67°34'W). October 1984. G. Scrocchi, E. Terán and O. Pagaburo. FML 1621 (1 specimen). 4 km Río La Puerta. 31 Km S Tinogasta (28°04'S, 67°34'W) on ruta Provincial Nro. 45. October 1984. G. Scrocchi, E. Terán and O. Pagaburo. FML 1623 (2 specimens). Near Ruta Nacional 60, 33 km S Tinogasta (28°04'S, 67°34'W). October 1998. F. Lobo and M. Halloy. FML 7711. Villa Luján (28°16'S, 67°23'W, specimens Río Colorado). 21 May 1988. G. Scrocchi and P. Blendinger. FML 2134 (1 specimen). These are the first vouchered records for Pomán and second records for Belén Departments despite the imprecise type locality records in the mountains near Belén (Hellmich, 1964). Cei's (1993) citations for Belén localities are unvouchered. It is our experience that *L. robertmertensis* is typically found in association with rocky hillsides, but in the eastern edge of the Salar de Pipanaco, this species is found in open woods of *Prosopis* and shrubs with sandy and salty soils. Department Andalgalá citations are the first vouchered records. Medanitos and Termas de Fiambalá localities are the westernmost records for this species, first records for Sierra de Fiambalá formation, and extends the range ca. 55 km (airline) W of the type locality. Localities near Tinogasta, Villa Luján, and Río La Puerta extend the range ca. 90 km SW (airline) of the type locality in Catamarca Province. All records are the first for Tinogasta Department. LA RIOJA PROVINCE: Famatina Department: "Chiquero del Pío," near Antinaco (28°49'S, 67°19'W), Sierra de Velazco (3000 m). December 1985. E. Pereyra, O. Pagaburo, and J. Bracamonte. FML 1792 (1 specimen). "Saladillo," near Antinaco (28°49'S, 67°19'W). Sierra de Velazco (1900 m). December 1985. E. Pereyra, O. Pagaburo, and J. Bracamonte. FML 1793 (1 specimen). Arauco Department: 2 km N Señor de la Peña (28°44'S, 66°47'W) 17 October 1998. L. Avila, L. Belver and F. Lobo. FML 7746. 4 km N Señor de la Peña (28°44'S, 66°47'W). 17 October 1998. L. Avila, L. Belver and F. Lobo. FML 7747. La Calera (near Señor de la Peña), 20 km E de Anjullón (28°44'S, 66°56'W). 22 February 1972. R. F. Laurent. FML 525 (1 specimen). First records for La Rioja Province, southernmost records for the species, first record for Sierra de Velasco formation, and extends range ca. 150 km (airline) S of the type locality.

Liolaemus bitaeniatus

CATAMARCA PROVINCE: Belén Department: 2.5 km W Condor Huasi (27°30'S, 67°07'W). 14 November 1998. F. Lobo and L. Avila. FML 7705. Valle Viejo Department: Sierra de Ancasti. 27 km de Portezuelo. 28 December 1982. A. Marcus. FML 1689 (3 specimens). First vouchered records for Belen and Valle Viejo departments. Cei's (1993) citations for Catamarca Province are unvouchered.

New County Records of Amphibians and Reptiles from Northern Indiana

ROBERT BRODMAN
Biology Department, Saint Joseph's College
Rensselaer, Indiana 47978, USA
e-mail: bobb@saintjoe.edu

The distribution of amphibians and reptiles in Indiana, USA, has been documented by Minton (1972) and Minton et al. (1982). However, distributional records are lacking in many counties, including those of the Grand Prairie and Bluffton till plain sections of northern Indiana. Voucher specimens of new county records are reported here from Newton, Jasper, Pulaski, Benton, White, Miami, Wabash, Huntington, and Adams counties. Identification of *Ambystoma jeffersonianum/Ambystoma laterale* complex and *A. texanum* were verified electorphoretically by James P. Bogart. All other specimens were verified by Sherman A. Minton, Jr. Voucher specimens and color photographs were deposited in the Saint Joseph's College zoological collection (SJC). Except where noted, all specimens were collected by the author.

CAUDATA

Ambystoma jeffersoniaum (Jefferson Salamander). WABASH CO: Salmonie Lake State Forest. 12 April 1998. SJCAM 101. Four larvae taken and raised to metamorphosis in the lab, several egg masses seen in the field. HUNTINGTON CO: 1 km S Salmonie Lake. 4 June 1998. SJCAM 126. One larvae taken and raised to metamorphosis in the lab. All five specimen from these sites were LJJ triploids. These records fill the gap between Allen and Clinton counties.

Ambystoma laterale (Blue-spotted Salamander). PULASKI CO: Berns-Meyer Nature Preserve, 3 km NE Pulaski. 12 May 1997. SJCAM 102. Five larvae taken and raised to metamorphosis in the lab, several more seen. These were all pure LL diploids. Unidentified members of the *Ambystoma jeffersonianum* complex were previously collected from Pulaski County (Minton 1972). Extends the range ca. 30 km S of nearest record in Starke County.

Ambystoma maculatum (Spotted Salamander). PULASKI CO: Berns-Meyer Nature Preserve, 3 km NE Pulaski. 12 May 1997. SJCAM 103. Two larvae taken. Fills distribution gap in northwest Indiana between Marshall and Clinton counties and extends the range ca. 35 km to the W in this portion of the state.

Ambystoma texanum (Smallmouth Salamander). HUNTINGTON CO: Salmonie Lake State Recreation Area. 12 April 1998. SJCAM 105. Five larvae taken and raised to metamorphosis in the lab, dozens of egg masses seen in the field. Fills the gap among surrounding counties. WHITE CO: Lowe's Nature Preserve, 3 km E Monon. 18 April 1998. SJCAM 104. Three larvae taken, two were raised to metamorphosis in the lab. Extends range ca. 50 km W of Cass County and ca. 70 km NE of Warren County.

Ambystoma tigrinum (Eastern Tiger Salamander). PULASKI CO: Berns-Meyer Nature Preserve, 3 km NE Pulaski. 12 May 1997. SJCAM 106. Four larvae taken, many others seen. NEWTON CO: Willow Slough Fish and Wildlife Area. 6 June 1997. SJCAM 107. Four larvae taken. These records complete the county sequence in NW Indiana to the Illinois border. HUNTINGTON CO: Salmonie Lake State Recreation Area. 12 April 1998. SJCAM 108. Four larvae taken, dozens of egg masses seen.

Notophthalmus viridescens viridescens (Red-spotted Newt). JASPER CO: Jasper-Pulaski Fish and Wildlife Area. 15 June 1997. SJCAM 109. One voucher specimen and photos of adults were taken from four ponds. Extends the range in NW Indiana ca. 50 km S of nearest record in Porter County, and ca. 50 km W of nearest record in Pulaski County.

Siren intermedia (Lesser Siren). PULASKI CO: Jasper-Pulaski Fish and Wildlife Area. 15 November 1996. SJCAM 110. Two adults were taken from a ditch along SR 421. This species had been reported from a site in Jasper County. Fills gap between Starke and White counties.

ANURA

Bufo americanus (American Toad). PULASKI CO: Berns-Meyer Nature Preserve, 3 km NE Pulaski. 2 June 1997. SJCAM 111. One adult male taken from a small chorus. WHITE CO: Lowe's Nature Preserve, 3 km E Monon. 18 April 1998. SJCAM 114. One adult male taken from a large chorus. MIAMI CO: 1 km S Macey. 12 April 1998. SJCAM 112. One adult male taken from a large chorus. HUNTINGTON CO: Salmonie Lake State Recreation Area. 12 April 1998. SJCAM 113. One adult male taken from a moderate sized chorus. These record complete a series from Adams County on the Ohio border to Newton County on the Illinois border.

Bufo fowleri (Fowler's Toad). HUNTINGTON CO: Majenica Marsh, 1 km E Salmonie Lake State Recreation Area. 4 June 1998. SJCAM 127. Numerous tadpoles were seen; six tadpoles were taken and raised to metamorphosis in the lab. Fills gap between Allen and Wabash counties.

Pseudacris crucifer (Spring Peeper). MIAMI CO: 1 km S Macey. 12 April 1998. SJCAM 115. One adult male taken from a moderate sized chorus. HUNTINGTON CO: Salmonie Lake State Recreation Area. 12 April 1998. SJCAM 116. One adult male taken from a small chorus. BENTON CO: Robert Feldt Marsh, 13 km E Fowler. 17 April 1998. SJCAM 117. One adult male taken from a moderate sized chorus. These records complete a series from Allen County on the Ohio border to Benton County on the Illinois border.

Pseudacris triseriata (Western Chorus Frog). HUNTINGTON CO: Salmonie Lake State Recreation Area. 12 April 1998. SJCAM 118. One adult male taken from a moderate sized chorus. Completes series from Adams County on the Ohio border to Newton County on the Illinois border.

Hyla versicolor (Eastern Gray Treefrog). BENTON CO: Robert Feldt Marsh, 13 km E Fowler. 28 April 1998. SJCAM 119. One adult male taken from a moderate sized chorus. HUNTINGTON CO: Salmonie Lake State Recreation Area. 4 June 1998. SJCAM 128. Numerous tadpoles were seen; five were taken and raised to metamorphosis in the lab. These records complete a series from Adams County on the Ohio border to Benton County on the Illinois border.

Rana catesbeiana (Bullfrog). PULASKI CO: Jasper-Pulaski Fish and Wildlife Area. 11 June 1997. SJCAM 120. One adult taken from

small chorus. NEWTON CO: Willow Slough Fish and Wildlife Area. 6 June 1997. SJCAM 121. One adult taken from large chorus. BENTON CO: 3 km N Robert Feldt Marsh, 13 km E Fowler. 2 June 1998. SJCAM 132. One adult male taken from a moderate sized chorus. MIAMI CO: 1 km S Perrysburg. 4 June 1998. SJCAM 133. One adult taken from small chorus. WABASH CO: 11 km W North Manchester. 4 June 1998. SJCAM 129. One adult taken from small chorus. HUNTINGTON CO: Majenica Marsh, 3 km N Mt. Etna. 4 June 1998. SJCAM 130. One adult taken from small chorus. These records complete a series from Adams County on the Ohio border to Benton and Newton counties on the Illinois border.

Rana clamitans (Green Frog). PULASKI CO: Berns-Meyer Nature Preserve, 3 km NE Pulaski. 2 June 1997. SJCAM 122. One adult male taken from a small chorus. BENTON CO: 3 km N Robert Feldt Marsh, 13 km E Fowler. 2 June 1998. SJCAM 131. One adult male taken from a moderate sized chorus. MIAMI CO: 1 km S Perrysburg. 4 June 1998. SJCAM 132. One adult taken from small chorus. WHITE CO: Lowe's Nature Preserve, 3 km E Monon. 18 April 1998. SJCAM 126. One adult male taken from a small chorus. HUNTINGTON CO: Salmonie Lake State Recreation Area. 4 June 1998. SJCAM 124. Numerous adults were seen, one was taken. These records complete a series from Allen County on the Ohio border to Benton County on the Illinois border.

Rana pipiens (Northern Leopard Frog). MIAMI CO: 1 km S Macey. 12 April 1998. SJCAM 123. One adult male taken from a small chorus. Fills gap among surrounding counties.

Rana sylvatica (Wood Frog). PULASKI CO: Berns-Meyer Nature Preserve, 3 km NE Pulaski. 30 March 1998. SJCAM 125. One adult male taken from a small chorus. Extends range 17 km SW from nearest record from Starke County.

TESTUDINES

Terrapene carolina (Eastern Box Turtle). PULASKI CO: Berns-Meyer Nature Preserve, 3 km NE Pulaski. 12 May 1997. SJCRP 101. Carapace of a dead specimen (length 118 mm) and a color photograph of one large (carapace length 145 mm) female. Fills distribution gap between Jasper and Cass counties.

New Illinois Amphibian and Reptile Distribution Records from the Kaskaskia River Drainage

ALLAN K. WILSON
Department of Zoology, Southern Illinois University
Carbondale, Illinois 62901-6501, USA
e-mail: akwilson@siu.edu

The last large Illinois contribution to the Geographic Distribution section of *Herpetological Review* was Petzing et al. (1998). The 26 new county records and four within-state range extensions in this article are a result of field work carried out in the Kaskaskia River drainage of Clinton, St. Clair, and Washington counties in Illinois (USA) during 1997 and 1998. The amphibian and reptile species of this area had been poorly documented prior to this inventory. Most of the land in the study areas is privately owned and is not open to public access which may account for the lack of herpetofaunal records. Habitats in this area are diverse and include floodplain forests with vernal, buttonbush (*Cephalanthus*) swamps and permanent oxbows, upland oak-hickory dominated flatwoods with vernal pools, and man-made pools and ponds. The study areas are located within the "Kaskaskia Bottoms" which is the largest unfragmented forest tract in the state. Kaskaskia Bottoms is one of 30 resource rich areas in Illinois identified by the Illinois Department of Natural Resources and The Nature of Illinois Foundation (1996).

Specimens taken for vouchers are deposited in the collections of the Illinois Natural History Survey (INHS) and Southern Illinois University at Carbondale (SIUC). County records were verified by checking the Illinois Herpetological Vouchered Database in the Illinois Natural History Survey at Champaign, Illinois, which contains data on Illinois amphibian and reptile species from 30 U.S. collections. A web page developed from the database information has been created which provides county-level distribution data for Illinois herpetofauna. This web site is accessible through the URL: http://www.inhs.uiuc.edu/cbd/collections/herp.html.

CAUDATA

Ambystoma maculatum (Spotted Salamander). CLINTON CO: 6.8 km N and 0.8 km W Okawville. (SE 1/4 Sec. 29, T01N, R04W; UTM Zone 16: N4263690m, E276903m; 38°29'37"N, 89°33'29"W). 1 March 1998. Elizabeth A. Fusek and A. K. Wilson. Verified by J. E. Petzing. INHS 14084. Collected as an egg mass in a semi-permanent pool in a young oak-hickory flatwoods stand and raised to metamorphosis in lab by J. E. Petzing. New county record which extends the known range ca. 64 km to the NW of the nearest vouchered locality in Jefferson County; ST. CLAIR CO: 5.2 km NE Fayetteville and N end Wagon Lake Road (UTM Zone 16: N4253803m, E260574m; 38°24'01"N, 89°44'30"W). 5 April 1998. A. K. Wilson, E. A. Fusek, Richard Harms and David Harms. Verified by J. E. Petzing. INHS 13989. One adult collected at the edge of a floodplain forest. Previously unvouchered record. Smith (1961) reported to have examined specimens from St. Clair County but to-date none have been found in museum collections; WASHINGTON CO: 8 km W Okawville. (SE 1/4 SE 1/4 Sec. 21, T01S, R05W; UTM Zone 16: E268440m, N4256480m; 38°25'26"N, 89°39'07"W). 15 June 1997. INHS 13365. Verified by J. E. Petzing. Collected from ditch along east side of agriculture field and raised to metamorphosis in the laboratory by JEP. New county record.

Ambystoma opacum (Marbled Salamander). CLINTON CO: 6.7 km N and 0.8 km W Okawville. (SE 1/4 Sec. 29, T01N, R04W; UTM Zone 16: N4263730m, E276639m; 38°29'38"N, 89°33'40"W). 1 March 1998. E. A. Fusek and A. K. Wilson. Verified by J. E. Petzing. INHS 14080. Collected as larvae in a vernal pool near an oak-hickory flatwoods stand. New county record which extends the known range ca. 18 km to the W of the nearest locality in Washington County.

Ambystoma texanum (Smallmouth Salamander). WASHINGTON CO: 3.5 km NW Venedy near Calamus Lake. (SW 1/4 Sec. 21, T01S, R05W; UTM Zone 16: N4256423m, E267595m; 38°25'33"N, 89°39'44"W). 26 April 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13122. New county record.

Notophthalmus viridescens (Eastern Newt). WASHINGTON CO: 9 km W Okawville, temporary ditch E Calamus Lake. (SE 1/4 SE 1/4 Sec. 21, T01S, R05W; UTM Zone 16: N4256480m, E268440m; 38°25'36"N, 89°39'10"W). 6 July 1997. A. K. Wilson and J. E. Petzing. Verified by C. A. Phillips. INHS 13427. Larva collected from an agriculture field ditch and raised to metamorphosis by AKW.

New county record which extends the known range ca. 30 km ESE of the nearest locality in St. Clair County at Belleville.

ANURA

Bufo americanus (American Toad). CLINTON CO: 0.1 km N Co. Road 250N on Co. Road 100E and 1 km W New Memphis Station (border of SE 1/4 NE 1/4 Sec. 07 and SW 1/4 NW 1/4 Sec. 08, T01S, R05W; UTM Zone 16: N4260423m, E265673m; 38°27'41"N, 89°41'08"W). 7 September 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13447. Found dead on road (DOR). Previously unvouchered record. Smith (1961) reported to have examined specimens from Clinton County, but to date none have been found in museum collections; ST. CLAIR CO: just E of S end High Banks Road and 8.6 km SW New Memphis. (SW 1/4 Sec. 22, T01S, R06W; UTM Zone 16: N4256397m, E259929m; 38°25'25"N, 89°40'00"W). 1 June 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13118. New county record. Previously unvouchered record. Hurter (1911) reported an observation record for this species but no voucher was taken.

Bufo woodhousii (Woodhouse's Toad). WASHINGTON CO: 3.5 km NW Venedy near Calamus Lake. (SW 1/4 Sec. 21, T01S, R05W; UTM Zone 16: N4256423m, E267500m; 38°25'33"N, 89°39'48"W). 26 April 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13131. New county record.

Hyla chrysoscelis (Cope's Gray Treefrog). CLINTON CO: 6.6 km N Okawville and 0.7 km NE Shoal Creek-Kaskaskia River confluence. (SW 1/4 NW 1/4 Sec. 32, T01N, R04W; UTM Zone 16: N4262998m, E275936m; 38°29'14"N, 89°34'08"W). 8 June 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 14082. New county record. The species was verified by occilligram output of the calling specimen prior to capture; ST. CLAIR CO: Just E of South end of High Banks Road and 8.6 km SW New Memphis (SW 1/4 Sec. 22, T01S, R06W; UTM Zone 16: N4256397m, E259929m; 38°25'25"N, 89°45'00"W). 1 June 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13119. New county record. Species was verified by occilligram output from an audio recording of the calling specimen prior to capture.

Pseudacris crucifer (Spring Peeper). CLINTON CO: 6.8 km N and 0.8 km W Okawville. (SE 1/4 Sec. 29, T01N, R04W; UTM Zone 16: N4263733m, E276786m; 38°29'38"N, 89°33'34"W). 1 March 1998. A. K. Wilson and E. A. Fusek. Verified by J. E. Petzing. INHS 13896. Collected one adult male in a vernal pool in an oak-hickory flatwoods stand. New county record.

Pseudacris triseriata (Western Chorus Frog). CLINTON CO: 10.6 km E-SE Mascoutah at New Memphis on Ill. Rt. 177 (SW 1/4 Sec. 08, T01S, R05W; UTM Zone 16: N4260349m, E266467m; 38°27'39"N, 89°40'35"W). 8 March 1998. A. K. Wilson and E. A. Fusek. Verified by J. E. Petzing. INHS 13897. Adult male collected while calling in a roadside ditch. New county record.

Rana catesbeiana (Bullfrog). CLINTON CO: farm pond on S side Posey, 0.2 km S railroad crossing on Ill Rt.127 (NE 1/4 NE 1/4 Sec. 18, T01N, R02W; UTM Zone 16: N4267678m, E264926m; 38°32'02"N, 89°21'10"W). 22 April 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13120. Collected as a large larva in an extremely bloated state. New county record.

TESTUDINES

Chelydra serpentina (Common Snapping Turtle). CLINTON CO: 6.7 km N and 0.8 km W Okawville. (Sec. 32, T01N, R04W; UTM Zone 16: N4263573m, E276717m; 38°29'33"N, 89°33'37"W). 29 June 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13141. One AOR juvenile collected. Previously unvouchered record (Cahn 1937).

Terrapene carolina (Eastern Box Turtle). CLINTON CO: 6.8 km N and 0.8 km W Okawville. (SE 1/4 Sec. 29, T01N, R04W; UTM Zone 16: N4263733m, E276786m; 38°29'38"N, 89°33'34"W). 16 August 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13451. Carapace collected. New county record.

LACERTILIA

Eumeces laticeps (Broadhead Skink). ST. CLAIR CO: 4.8 km W and 3.5 km S New Memphis Station (Sec. 23, T01S, R06W; UTM Zone 16: N4257107m, E261458m, 38°25'49"N, 89°43'58"W). 21 June 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13135. Previously unvouchered record (Taylor 1935). The specimen referred to by Taylor has not been located, but another specimen was located at the U.S. National Museum of Natural History with the following information: ST. CLAIR CO: Belleville. September 1874. Dr. A. Reuss. USNM 8767. Catalogued on 15 March 1877. New county record not previously published. USNM 8767 was originally misidentified as *E. fasciatus* and later reidentified as *E. laticeps* by James A. Peters on 21 December 1964 (R. Reynolds, pers. comm.); WASHINGTON CO: 6.7 km W Okawville (SW 1/4 Sec. 14, T01S, R05W; UTM Zone 16: N4257465m, E270731m; 38°26'10"N, 89°37'36"W). 29 September 1997. L. Schuetz and A. K. Wilson. Verified by J. E. Petzing. INHS 13434. Juvenile. New county record. Previously unvouchered record. Smith (1961) reported to have examined specimens from Washington County, but to date, none has been found in museum collections.

SERPENTES

Nerodia erythrogaster (Plainbelly Water Snake). CLINTON CO: 6.7 km N Okawville. (NW 1/4 Sec. 32, T01N, R04W; UTM Zone 16: N4263089m, E275729m; 38°29'17"N, 89°34'17"W). 8 June 1997. A. K. Wilson. Verified by R. A. Brandon. SIUC R-3053. New county record.

Nerodia rhombifer (Diamondback Water Snake). CLINTON CO: 0.5 km W Kaskaskia River Bridge on Ill. Rt. 177 (Se 1/4 SE 1/4 Sec. 10, T01S, R05W; UTM Zone 16: N4258688m, E269694m; 38°26'48"N, 89°38'21"W). 16 June 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13117. DOR juvenile. New county record; WASHINGTON CO: 8.6 km W Okawville near Clear Lake (NW 1/4 SW 1/4 Sec 22, T01S, R05W; UTM Zone 16: N4256555m, E268980m; 38°25'39"N, 89°38'47"W). 13 September 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13437. Collected from a residential opening in an oak-hickory flatwoods. New county record.

Nerodia sipedon (Northern Water Snake). CLINTON CO: roadside pool on U.S. Rt. 50 below Carlyle Lake Dam (SE 1/4 Sec. 18, T02N, R02W; UTM Zone 16: N4276185m, E295216m; 38°36'38"N, 89°21'07"W). 22 April 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13113. Juvenile. New county record.

Regina grahamii (Graham's Crayfish Snake). CLINTON CO: 1.2 km W New Memphis Station and 1.2 km E St. Clair County line on Co. Road 250N (SE 1/4 Sec. 07, T01S, R05W; UTM Zone 16: N4260118m, E265177m; 38°27'31"N, 89°41'28"W). 14 June 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13413. Adult found AOR near a 10–20 year old timber stand surrounding a floodplain pond. New county record.

Storeria dekayi wrightorum (Midland Brown Snake). CLINTON CO: Gravel road 6.9 km NNW Okawville and 0.7 km NNW Shoal Creek/Kaskaskia River confluence (SW 1/4 NE 1/4 Sec. 31, T01N, R04W;

UTM Zone 16: N4263139m, E275729m; 38°29'18"N, 89°34'17"W). 8 June 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13416. Adult female collected which gave birth in captivity. New county record.

Storeria occipitomaculata (Redbelly Snake). WASHINGTON CO: 8.6 km W Okawville and S Clear Lake (SW 1/4 Sec. 22, T01S, R05W; UTM Zone 16: N4256617m, E269071m; 38°25'41"N, 89°38'44"W). 14 July 1997. A. K. Wilson, E. A. Fusek, and J. B. Taft. Verified by J. E. Petzing. INHS 14079. Collected near a residential opening in an oak-hickory flatwoods. New county record.

Thamnophis proximus (Western Ribbon Snake). ST. CLAIR CO: 6.75 km SW New Memphis Station (SW 1/4 NE 1/4 Sec. 23, T01S, R06W; UTM Zone 16: N4257149m, E261702m, 38°25'51"N, 89°43'48"W). 25 May 1997. A. K. Wilson. Verified by J. E. Petzing. INHS 13112. This specimen extends the species known range to the E and is 41 km ESE of the nearest vouchered locality record at Cahokia. This voucher is also the first of this species to be taken in the Kaskaskia River drainage.

Acknowledgments.—I thank John E. Petzing and Christopher A. Phillips for reviewing the manuscript. The Illinois Natural History Survey provided needed field equipment and museum records information. Elizabeth A. Fusek, John E. Petzing, Glen Schuetz, Nathan Schuetz, Jennifer Malacarne, William J. Poly, and Steve Daniels assisted with field work. Mike Redmer provided oscillograms of pre-recorded anuran calls. Robert Reynolds provided museum records information from the U.S. National Museum of Natural History. Field work was supported by funding from the Wildlife Preservation Fund and the Conservation 2000 Fund, both of the Illinois Department of Natural Resources. Many thanks are due to the study area landowners for their cooperation in this project.

Reichard et al. (1995) identified southwestern Kansas, USA, as an area where information is limited about the distribution of reptiles and amphibians. We surveyed six counties (Haskell, Grant, Gray, Seward, Stanton, and Stevens counties) in southwestern Kansas from April through August 1996. In addition, a notable frog record was obtained from Rush County.

Amphibians and reptiles were considered as new county distribution records if they were not reported in Collins (1993), or in a subsequent issue of the *Kansas Herpetological Society Newsletter*. All specimens were collected by the authors, deposited in the herpetological collections of the Sternberg Museum of Natural History (formerly Museum of the High Plains), and verified upon accession by Eugene D. Fleharty. New county distribution records are as follows:

ANURA

Rana catesbeiana (Bullfrog). GRANT CO: Ulysses Golf Course. (MHP 6715). 3 May 1996. County record; captured in a water hazard. RUSH CO: 10.5 km S Rush Center (MHP 6716). 26 July 1996. County record; found dead on US Rt. 183. STEVENS CO: 8.9 km N and 4 km W Feterita (MHP 6717). 29 June 1996. County record; captured from a windmill-fed pond.

TESTUDINES

Chelydra serpentina (Common Snapping Turtle). GRANT CO: 0.8 km N and 3.6 km E Ulysses. (MHP 6718). 4 May 1996. County record; captured in water pooled under a railroad bridge.

Kinosternon flavescens (Yellow Mud Turtle). STEVENS CO: 1.6 km N and 4 km E Cave. (MHP 6724). 30 June 1996. County record; found dead on US Highway 56.

Terrapene ornata (Ornate Box Turtle). GRANT CO: 5.6 km N & 5.6 km E Ulysses. (MHP 6719). 4 May 1996. County record; captured at an abandoned gravel pit.

Trachemys scripta (Slider). GRANT CO: 0.8 km N and 3.6 km E Ulysses. (MHP 6720). 4 May 1996. County record; captured from water pooled under a railroad bridge. GRAY CO: 1.2 km S Cimarron. (MHP 6721). 16 June 1994. County record; shot while sunbathing on a log, which was floating in a gravel pit.

LACERTILIA

Sceloporus undulatus (Prairie Lizard). STEVENS CO: Cimarron National Grasslands, 9.7 km N and 3.2 km W Feterita. (MHP 6722).

29 June 1996. County record; captured under a fallen tree.

SERPENTES

Arizona elegans (Eastern Glossy Snake). STEVENS CO: Cimarron National Grasslands, 9.7 km N and 3.2 km W Feterita. (MHP 6723). 29 June 1996. County record; captured while crawling through vegetation.

Five of the nine specimens reported herein were captured from artificial pools of water. These records may represent animals overlooked by previous surveys, but it is possible they represent the first evidence of a more interesting phenomenon—the invasion of artificial water sources by wildlife.

The Ogallala aquifer underlies the western one-third of Kansas. Southwestern Kansas is the most heavily irrigated area of the state (Socolofsky and Self 1988). Jenkins (1983) reported that irrigation wells pump ca. 6,615 hm^2 (5,000,000 acre/ft) per year to irrigate 1,214,100 hm^2 (3,000,000 acres) of agricultural land. This high rate of water removal from the aquifer combined with a low recharge rate from precipitation (typically 40–56 cm/yr) has led to a declining water table (Socolofsky and Self 1988). One effect of lowering the water table is a reduced amount of surface water in the natural springs, rivers, and streams (Kromm and White 1992).

In contrast, numerous artificial water sources have been created, either as a result of irrigation for agriculture, or for recreational or municipal use. These new water resources include farm ponds, gravel pits, stock tanks, municipal reservoirs, and state fishing and recreation lakes. The net effect of this change with regard to the amount of surface water in southwestern Kansas is presently unknown. However, the nature of the surface water has undoubtedly changed since the introduction of large-scale irrigation in the region. This change in the nature of surface water in a relatively short time-period may impact the distribution of organisms associated with water. Some of the new records reported herein could be the result of a distributional shift of these species in response to a change in the availability of appropriate aquatic habitats.

Acknowledgments.—This study would not have been possible without the cooperation of the following people and organizations who allowed us access to land they either managed or owned, and offered their knowledge of local animals: D. Bozone; M. Christianson; J. Cline, Cimarron National Grasslands; R. Daniels; S. Dorris; D. Foreman, R. Fox, J. Krie; J. C. Nelson; J. Smith; T. Stewart; and J. Unsell. Ken Brunson (Kansas Department of Wildlife and Parks) provided us with a permit that allowed us to maintain the *Arizona elegans* captured during this study. We are also indebted to the following people who provided assistance both in the laboratory and in the field: K. C. Chapman, S. M. Hilgers, S. R. Hoofer, L. and M. Walker, and J. and L.Watson.

The Amphibians and Reptiles of the Yucatán Peninsula, by Julian C. Lee. 1996. Cornell University Press, Ithaca, New York. i–xii, 500 pp., 403 figures (210 in color), 188 maps. Hardcover. US $175.00.

This is a book written for professional herpetologists, but it can also be very instructive for amateurs. Julian Lee should be regarded as Mr. Yucatán herpetologist, as there is no other person who knows better the herpetofauna of this part of the world.

This book is organized into six parts (these are not numbered as chapters or sections): Introduction, The Environment of the Yucatán Peninsula, Habitats of Amphibians and Reptiles, A Brief History of Herpetology in the Yucatán Peninsula, and Species Accounts. At the end of the species accounts section, there is a small section on Ethnoherpetology that probably should be a separate section. At the end of the main text, there is a Gazetteer and a Glossary. There are Subject and Taxonomic indices.

Amphibians and Reptiles of Northern Guatemala, the Yucatán, and Belize, by Jonathan A. Campbell. University of Oklahoma Press, Norman, Oklahoma. i–xix, 380 pp., 189 figures (176 in color). 1998. Hardcover US $100.00; softcover US $29.95.

This is a semi-popular book, which can be of widespread use for professionals as well. Jon Campbell is a well known herpetologist, with vast field experience in Guatemala and México.

This book is organized into three main sections. The Introduction contains a brief history of exploration in the area, as well as information on identification, conservation, and how to find herps. The other two sections are devoted to Amphibians and Reptiles, respectively. Six appendices (with taxonomic keys) and a glossary are at the end of the book. The section containing species accounts includes 15 boxed natural history vignettes, including personal adventures, that are fun to read. There is an alphabetical index of scientific names, place names, and general terms.

The quality of the printing in both books is very good, with a nice organization and excellent photographs. It is hard to compare them, especially when they are not intended for the same audience, but I will try. Lee's book is a work for an audience of mostly herpetologists and amateurs that are herpeto fans. The book has numerous drawings, photographs (most of them of a very good quality), and distributional maps, as well as several color photographs showing habitats in the peninsula. Many of the drawings illustrate the terms used to identify the species in question. The book presents in each section bilingual identification keys (in English and Spanish), that in fact work very well. Lee´s book has tadpole keys which are absent from Campbell's. Each species account in Lee's book is very detailed, including information on the original description, holotype and type locality, a description, similar species, distribution, natural history, subspecies, etymology, a comment section, and locality records in the peninsula. Each account also contains distribution maps, drawings of tadpoles for most of the species with indirect development (frogs and toads), and audiospectrograms of ad-

vertisement calls. One hundred and eighty-six color photographs illustrate 148 species. The accounts range from about a page to three and a half pages. A ten-page glossary, with about 400 definitions and terms, completes Lee's book.

Campbell´s is a book for a general audience, and is replete with numerous photographs, most of them of very good quality. It includes black-and-white habitat photos, two maps of the area covered by the book, and four plates with numerous drawings. Unfortunately, there is no a general lepidosis with nomenclature for the lay person, even when some of those terms are used in the species descriptions. This book, as well as Lee´s, has identification keys. In Campbell´s book these are included in an appendix, and are bilingual which make the keys very useful for both North Americans and native scholars who do not speak English. Each species account presents a detailed description, natural history (these vary in length according to how much is known for each particular species), distribution, and many accounts offer a small section with general remarks. The species accounts are easy to read for the person familiar with herpetological terminology, and all are very informative. There are 175 photographs that illustrate all of the amphibians and all of the reptiles but two species (*Ameiva chaitzami* and *Rhadinaea anachoreta*). The accounts vary in length from about half of a page to two and a half pages. A nine-page glossary containing just over 200 terms is at the end of the text.

Numerous original, natural history observations permeate both books, which testifies to the field experiences of both authors, and adds considerably to the reference value of each work.

There are a few differences in the treatment of some taxonomically problematic groups. For example, Lee treats anoles as the genus *Anolis*, while Campbell places them in *Norops*. Lee uses *Urotheca* and *Celestus* for Campbell's *Pliocercus* and *Diploglossus*, respectively. There are also a few differences at the species level. Within the anoles, what Lee calls *pentaprion* is referred to as *beckeri* by Campbell; Lee's *lemurinus* is Campbell's *burgeaei*. Lee uses *Mabouya unimarginata, Cnemidophorus cozumela*, and *Leptodeira septentrionalis* for species Campbell refers to as *M. brachypoda, C. maslini*, and *L. polysticta*, respectively. *Bufo campbelli* is part of *B. valliceps* in Lee´s book, maybe because the species description was not published when the Yucatán book was already in press. Also *Rhadinaea anachoreta* is not included in Lee´s book, possibly for the same reason.

Both authors used common names, although Lee not only used an English name but also the local names for different parts of the peninsula (including some Mayan names), and had the good idea to not translate them into Spanish. Many of the common names used by Campbell are made up for this book and then translated into Spanish, making for some odd-sounding names. This kind of practice has been done in the past with very little success. Common names without relation to local meaning and that sound unnatural in Spanish have no practical utility.

Campbell arranged the identification keys in several appendices, while Lee inserted them directly in the text; each approach offers certain advantages. I hope that future works in English include bilingual identification keys as standard practice. There are several Latin Americans that will benefit from this practice and who would be willing to translate keys into Spanish, as I did for Lee´s book. I have made extensive use of his keys and they work just fine. I have not had the chance to test Campbell´s keys.

These two books are of the highest quality, both by their contents and the quality of printing. In brief, I highly recommend both, especially if you are a bibliophile. Julian Lee´s book certainly sets a standard for future regional monographic works, which will be difficult to meet, whereas Campbell´s is an excellent contribution to the semi-popular literature of the region. The major problem with Lee´s book is its price, in particular for Mexicans students, which may preclude the book's inclusion in many institutional and personal libraries in México.

TABLE 1. Species distribution in Lee's and Campbell's books.

	Lee	in common	Campbell
Caecilians	2	2	2

In 1966, Bob Inger treated the entire Bornean amphibian fauna in a monographic review (still available, thanks to a 1990 reprint from Malaysia). Still a classic, it contained detailed morphological descriptions, keys, ecological notes, and discussion on the systematics, nomenclature, and biogeography of a highly interesting fauna. Now, over three decades later, Inger, Emeritus Curator at the Field Museum of Natural History, has teamed up with Robert B. Stuebing, formerly Associate Professor, Universiti Kebangsaan Malaysia–Sabah Campus, to produce a more accessible guide to the fauna. The same team of authors gave us a field guide to the frogs of Sabah (Inger and Stuebing 1989). This particular publication sets an even higher standard for regional field guides, for which part of the credit should go to Natural History Publications (Borneo). The long list of books on the region's natural history published by this company also includes the admirable little book by Inger and Tan (1996) on the natural history of Sabah's amphibians and reptiles.

There have been considerable changes in the faunal list of this island, thanks largely to the efforts of these two authors. The 1966 monograph listed 88 species of amphibians as occurring on Borneo. The checklist in the present work shows 142 species (excluding the five caecilian species; see Frost 1985). During the 30 years that have elapsed between the publication of the two volumes, new areas have been inventoried, taxonomically cryptic species dealt with, and questions on the higher relationships in amphibians of the region addressed. This has resulted in many generic changes (not all of which, however, have been accepted by the authors). The present work concentrates on the adult anuran amphibians: caecilians are not dealt with, and tadpoles of anurans, when known, are briefly

described, but not illustrated. In all, 97 species are covered in detail.

The contents of the book include a Foreword by Sabah State's Deputy Chief Minister; a Preface (overlooking a magnificent portrait of a rainforest stream); followed by chapters on the general biology of frogs, frogs in local culture (including folklore and as food), the distribution and classification of Bornean frogs (including a key to adult frogs and a checklist of the anuran amphibian fauna of Borneo). Two important chapters deal with the ecology of frogs and their larvae, and will serve as a useful guide for field collectors, and finally, the all-important issue of conservation. Individual species accounts include the current scientific name and authority; a recommended English name; descriptions of adults, including size ranges for mature males and females; descriptions of tadpoles, including notes on their habitats; habits and habitat of adults; a description of calls; and distribution within (and when relevant, beyond) Borneo. Generic treatments are not just brief taxonomic definitions, but field notes on natural history of frog and toad groups, which make them invaluable for field identifications as well as museum collection work. What makes this book unique is that, between them, the two authors have nearly 70 years of field experience on Bornean frogs, which is abundantly clear in the species descriptions. Further, both wield the pen and the camera with equal dexterity. The high quality photographs of virtually every species they choose to describe attest to their industry. All photographs are of live amphibians, the only "museum piece" being the apparently rare *Barbourula kalimantanensis*. A list of ten references rounds out the book. As mentioned by Inger and Stuebing, the inventory of Borneo's amphibian fauna is far from complete. Most of the new discoveries have been made from the more accessible Malaysian states of Sarawak and Sabah, while the Indonesian sector, Kalimantan, has remained largely unknown. One hopes that future generations of biologists will explore these dark forests, armed with an adequate supply of collector's paraphernalia, and of course, a copy of Inger and Stuebing's amazing field guide.

With the production of these two volumes, the monograph series produced by the Spanish Association of Herpetologists provides both a review of general biogeographic theory and principles, and an analysis of the biogeography of the Iberian herpetofauna. *Objectivos y Métodos Biogeográficos* is a slim, well-produced volume providing an informative primer to the history, principles, and results of various approaches to the study of herpetological biogeography. Eight authors contribute to the nine chapters comprising the book; each chapter can be read (and understood) either as a single (and quite independent) entity, or as a chapter in a much larger story.

The volume opens with a brief preface, followed by three chapters introducing conceptual origins and development of the study of biogeography (J. M. Vargas), objectives and methods of various analyses (R. Real and J. M. Ramírez), and effects of scale on a study's result (A. Antúnez and A. L. Márquez). Following this introduction are three chapters detailing methods of preparing an atlas of species distribution (L. J. Palomo and A. Antúnez), determining factors contributing to the geographic range of a species (A. Antúnez and M. Mendoza), and elucidating biogeographical units (R. Real, J. M. Vargas, and J. C. Guerrero). The final three chapters discuss patterns of species richness (R. Real), contributions to environmental management and species conservation (J. M. Ramirez and J. M. Vargas), and schools and trends in historical biogeography (J. M. Vargas).

All contributions serve well as summaries of our state of accomplishment and understanding within this field of study. I found the chapter on the prospective role of biogeography in environmental management and species conservation to be particularly relevant, especially in today's world of declining natural environments, endangered species, and disappearing ecosystems.

As I read through these essays, I wondered for whom this volume was intended. There can be only one practical application for this monograph—to support the student conversant in Spanish who has an interest in biogeography. As the centerpiece for a seminar on biogeography—herpetological or otherwise—this volume would be excellent. If you teach in a setting where the instructional language is Spanish, or if you have a general interest in biogeography, you will want to consider purchasing this monograph.

Distribución y Biogeografía de los Anfibios y Reptiles en España y Portugal summarizes data resulting from the project "A Provisional Atlas of the Amphibians and Reptiles of Spain and Portugal." Sixty-four authors document and summarize the distribution

and biogeography of the Spanish and Portuguese (including non-continental possessions) herpetofauna. The first section ("Introduction," 24 pages) is partitioned into three chapters that provide background information regarding the original project, document the methodology employed, and review the history of biogeographic work concerning the herpetofauna. The second section ("The Iberian Peninsula") contains five chapters: "Origins and evolutionary relationships of the Iberian herpetofauna" (54 pages, illustrated with maps [some in color] and diagrams); "The Iberian herpetofauna" (206 pages, including distribution maps and color photographs of the species); "Biogeography of the amphibians and reptiles of the Iberian peninsula" (14 pages); "Altitudinal distribution of the Iberian herpetofauna" (21 pages, including histograms of elevational ranges for 63 species); and "The islets and small islands of littoral Iberica" (7 pages with maps, faunal lists, and color photographs).

Section Three, "The Balearics", presents the herpetofauna of the Balearic Islands in one chapter (16 pages, with maps and color photographs), and the biogeography of the islands in another (9 pages, including a table listing all named islets, their surface areas, elevations, and reptile and amphibian inhabitants). Section Four reviews the herpetofauna and biogeography of the Canary Islands, the Azores, and the Islands of Madeira and Salvajes in two chapters (45 pages with maps and color photographs). Section Five, aptly named "Miscellany", includes accounts of five marine turtles (18 pages, including maps and color photographs), the amphibians and reptiles of Ceuta, Melilla, Isla Chafarinas and (the large rocks of) Alhucemas and Vélez de la Gomera (14 pages, including a generalized map, species checklist, and 21 color photographs), and the species known to be introduced (11 pages, including photographs and maps). The volume concludes with a chapter on legislation, protection, and the state of conservation of the Spanish amphibians and reptiles (40 pages, including a table) followed by a similar chapter devoted to the amphibians and reptiles of Portugal (13 pages). The table of contents is located in the rear of the volume.

The first section of this volume is interesting and generally well written; it provides the background information one will need to make the most of this contribution. I must confess, however, that I do not care much for the mapping procedure. Provincial boundary lines are not provided, making orientation (especially mid-peninsula) more difficult than necessary. Although I certainly understand why decreasing quadrant size increases resolution, I don't see how reducing quadrant size from 20 km x 20 km to 10 km x 10 km would move the actual locality for a terrestrial salamander from land to sea (see quadrant CF, Fig. 1, p. 30)! This problem, unfortunately, is not confined to the map chosen to illustrate and explain the mapping procedure; several maps throughout the volume suffer the same problem and users will want to pay close attention to the errata sheet provided with the volume before attempting to use any of the maps.

Barbadillo, García-París, and Sanchíz are to be congratulated for their complete and thorough review of the evolutionary history of Iberian amphibian and reptile species. Their presentation serves well as an up-to-date review of the fossil record and our understanding of phylogenetic relationships among most lineages. Molecular clock data for cladogenetic events are compared with paleogeographic data to provide the reader with a retrospective look into the biogeographic history of the regional herpetofauna, and color diagrams representing geographical change from late Cretaceous to most recent glaciation serve to make this chapter easily understood. Figure 29b (p. 82), however, was printed in error; a corrected version appears on the reverse of the errata sheet. If you study the evolution of the European fauna, or are interested in biogeography in general, you will find this section most rewarding.

Most readers, however, will be drawn immediately to the species accounts. Each account explains the distribution and habitat preference of each taxon while providing a (mostly) superb color portrait-like photograph of each, a map of its distribution, and a listing of the "most significant" references. In a volume produced with cooperation from 64 authors, it is difficult to control the level of thoroughness and accuracy for each contribution and some problems result. Busack and Salvador (1984), for example, published significant distributional data for *Hemidactylus turcicus, Coronella girondica, Natrix natrix,* and *Vipera latastei* but were not cited in the accounts for any of these species. And I have to wonder why Busack (1985) is considered a "most significant" reference to *Podarcis hispanica* when the research to which it refers was neither presented at the meeting for which the abstract was prepared, nor published. Omissions and errors such as these reduce the general utility of the accounts in which they occur, and made me wonder about the thoroughness of other accounts in this section of the book.

Vargas and Real's chapter on biogeography is rather a disappointment, given the excellent presentation of the same topic presented earlier. In a major work such as this, one expects a thoroughly researched treatment. There is little depth to this analysis, and I was left wondering why contributions to Iberian biogeography by Busack (1977, 1986), Busack and Jaksic (1982), Busack and Hedges (1984), Delibes and Salvador (1986), and Pleguezuelos and Moreno (1990), to name but a few, were not incorporated into the discussion.

Section Three considers only two amphibian and three reptile species from the Balearic Islands, yet several additional species are known to inhabit these islands. Only by perusing the species accounts presented for continental Iberia, and examining the maps, may one assemble a complete listing of the herpetofauna of these islands. Why was a checklist of species known to occur on these islands (cross-referenced to the account provided elsewhere) not provided? A similar problem arises in the chapter concerning introductions when intra- and inter-continental introductions are listed. Why, for example, are *Discoglossus pictus, Testudo graeca, T. hermanni,* and *Chamaeleo chamaeleon* considered in the section on the continental fauna if introductions are considered separately and these taxa are known to be introductions? Adding to the confusion, the dot indicating the introduction site of *Bufo mauritanicus* is placed incorrectly on the map, the illustration of *Anolis carolinensis* indicates a specimen from Barcelona but the map documents only a much more southern locality, and the illustration labeled *Chrysemys picta* (p. 474) is actually that of a juvenile *Pseudemys floridana.*

Impressed as I was by the chapter contributed by Barbadillo, García-París, and Sanchíz, the thoroughness of some of the species accounts, and the quality of the photographs, I cannot recommend this volume to those not already well acquainted with the fauna. In a volume whose main purpose is to present a complete account of faunal distribution, one expects the maps to be accurate and complete; casual inspection indicates that neither is the case for several of the species with which I am familiar, and the book falls short of its primary mission.

If your research interest is Iberia, or is associated with its fauna in any way, you will need to have this book for some of the data it contains. But I caution against considering this volume a standalone reference to current knowledge regarding the Iberian fauna. The generalist will find the presentation enticing, even exciting, but the researcher requiring accurate distribution maps and complete summaries of the literature will find that reference to Salvador (1985, 1998) and García-París (1985) remains essential.

Scientific curiosity is piqued by uncommon biological phenomena. That which is rare demands explanation. For these reasons, herbivorous reptiles have captured the attention of herpetologists for decades. Indeed, fewer than 1% of nonavian reptiles—both extinct and modern—were, or are, herbivorous. The paucity of herbivorous reptiles has been attributed to numerous factors including constraints associated with morphology, physiology, behavior, biogeography, evolutionary history, and divergence capabilities. Yet, despite a long and rich history of interest, no comprehensive treatise has been provided for this understudied trophic group of the Reptilia. This void is now partly filled by Gillian King's *Reptiles and Herbivory*.

King, a paleontologist specializing in mammal-like reptiles (primarily dicynodonts), has produced a book that convenes much of the disparate literature on both extant and extinct reptilian herbivores. *Reptiles and Herbivory* provides a blend of taxonomic and functional perspectives on the shared challenges and specializations associated with a herbivorous lifestyle. The book is organized into seven chapters, most of which are titled by taxonomic group (e.g., Lizards, Mammal-like Reptiles, etc., see below). For this review, I will focus primarily on the two chapters concerning extant herbivorous reptiles (lizards and chelonians) because of both space constraints and the predominantly neontological interests of readers of *Herpetological Review*. Those interested in a paleontological perspective are directed to Weishampel (1996).

The first chapter discusses herbivory and reptiles in general and provides some working definitions. For 'herbivore,' King adopts a pluralistic definition: "...eating any part of a plant: root, stem, leaf, seed, fruit and so on" (p. 2). However, little discussion is provided here or elsewhere regarding the biological relevance of different types of plant tissues. It would be informative to consider how particular plant tissues (e.g., fruits vs. leaves) translate into certain opportunities and challenges for some herbivorous reptiles. It also would have been helpful if King had defined herbivore in terms of the minimum proportion of plant materials required to be in the diet to be classified as a herbivore. The diets of many reptiles lie on a continuum from carnivory to herbivory, and it is not clear if the author would categorize a lizard with a 75% plant diet as a herbivore. Despite acknowledging its limitations, King also follows the Linnean hierarchical system for defining 'reptile' and specific reptilian groups (following Carroll 1988). While this decision may raise eyebrows among contemporary systematists who advocate phylogenetically based taxonomies (e.g., de Queiroz and Gauthier 1994), King maintains that her primary interest is in discussing particular life strategies, not taxonomic relationships (p. 4).

Chapters two through five summarize most of what is known about herbivory in specific taxonomic groups: (2) Lizards; (3) Turtles and Tortoises; (4) Dinosaurs; and (5) Mammal-Like Reptiles. Chapter six provides a discussion of a hodgepodge of "Other Herbivores," all of which are extinct. Included in this chapter is a discussion of the Malawi crocodile (*Malawisuchus*) from the Lower Cretaceous which is one of at least two Mesozoic crocodylians considered to be herbivorous (see also Wu et al. 1995). The perspective in these chapters is principally functional morphological, but King does a commendable job of integrating much of what is known about the physiology, behavior, and ecology of members of these groups as well. I found the chapters dealing with extinct herbivorous reptiles to be both comprehensive and detailed. The information provided in the two chapters on extant groups was, however, somewhat less exhaustive. This is undoubtedly a reflection of King's principal research interests.

At the beginning of the 'Lizard' chapter, King provides a table of "Herbivorous lizards—important genera." This list is, however, incomplete. Notably, missing genera include: *Hydrosaurus* (Agamidae; Pough 1973), *Phymaturus* and some *Liolaemus* (Tropiduridae; Cei 1986; Troyer 1988, 1991), *Cnemidophorus* (*C. arubensis* and *C. murinus*; Schall and Ressel 1991; Dearing and Schall 1992, respectively [although both species are discussed later in the text]), and *Angolosaurus* (Gerrhosauridae; Pietruszka et al. 1986). It could be argued that these do not constitute "important genera," but within this same table King also includes other genera of questionable importance. For example, *Klauberina* (now *Xantusia riversiana*) is listed, but this species is usually considered an omnivore (Johnson and Lillywhite 1979), as are most species of *Tiliqua* and *Egernia* (Dubas and Bull 1991; Cogger 1992). Later in this chapter, King draws on evidence from studies of juvenile (< 20 g) herbivorous lizards to appropriately dismiss the 100-g minimum body-size hypothesis for herbivorous reptiles. Minor criticisms of this chapter include the use of "babies" for referring to juvenile nonhuman animals, the misspelling of *Uromastyx* (as *Uromastix*), and not following generally accepted taxonomic revisions (e.g., Frost and Etheridge [1989] for iguanian lizards). Also lacking in this chapter is a discussion of the role of omnivory as an evolutionary transition to herbivory. Many lineages of otherwise insectivorous lizards contain one or more species that are known to eat considerable amounts of plant matter, yet lack the adaptations seen in entirely herbivorous lizards. These may represent important cases of dietary "evolution in action" and, as such, warrant further consideration.

In the turtle and tortoise chapter, King contrasts the proportionately more successful herbivorous chelonians (ca. 25%) to the relatively uncommon herbivorous lizards (ca. 3%). She attributes this

disparity to the more robust skull, lack of teeth, moderate chewing abilities, and protective shell in chelonians, but finds no evidence for comparable physiological differences between the two groups. However, when examined from a phylogenetic perspective, chelonians have fewer independent radiations into the herbivorous lifestyle than lizards. This is because the vast majority of herbivorous chelonians are in the Testudinidae (tortoises). If the common ancestor of this clade was herbivorous (which seems likely), then herbivory probably evolved only once in this lineage prior to its radiation. Some ecological interactions are also overlooked. For example, the possibility that modern herbivorous reptiles may be (or have been) important seed dispersers or pollinators is not addressed.

Although a summary is provided at the end of each chapter, few novel insights are extracted from the admittedly meager, and diffuse data. Therefore, I hoped that the final chapter, "Patterns of Reptilian Herbivory," would provide a synthesis of the entire book and provide some new directions for research. Instead, King provides a temporal distribution—from the Late Paleozoic to the present—of various lineages of herbivorous reptiles. The various strategies for being herbivorous are compared among these groups. She finishes the chapter with a list of morphological specializations shared by members of various herbivorous reptilian lineages. Two take-home messages are woven throughout. First, despite their diverse evolutionary histories, herbivorous reptiles share numerous convergently evolved specializations. These include changes in the skull, teeth, gut, physiology, and behavior, as well as the acquisition of gastrointestinal microsymbionts. Second, the paucity of herbivorous reptiles, present and past, cannot be explained by their 'inferior design' or any other single factor.

In places, *Reptiles and Herbivory* is unavoidably laden with technical terminology—owing primarily to anatomical descriptions—otherwise, King keeps the language simple and her points are easily understood. This will likely make the book accessible to a wider audience; however, a familiarity with basic anatomy (primarily osteology) is assumed, albeit not explicitly. Most of the text is written in an authoritative style, with citations included only when studies are specific. While this editorial style may provide a smoother text flow, on a few occasions I found myself with no means of differentiating the author's ideas from her abstractions of the literature. The text is relatively free of typesetting mistakes, and the few missing words or grammatical errors that I detected were not distracting. Most of the figures are line drawings (redrawn from other sources) and are of excellent quality. There are no photographs. A short (six page) literature cited section and taxonomic and subject indices are included. The pages are of heavy weight and my frequent highlighting of sections with a solvent-based marker did not bleed through to the other side. The binding is sturdy and the hard cover is quite durable.

This is not the type of book that will incite much controversy, but it provides a laudable service by uniting most of what is known about herbivorous reptiles. I suspect history will show that this book's greatest contribution was in rejuvenating research on herbivorous reptiles. Clearly, there is still much to be learned. In contrast to most books that cover both modern and extinct taxa, neontological herpetologists may be disappointed by the greater emphasis on extinct forms, whereas paleontologists will likely stand up and cheer! Yet, at nearly $0.50 (US) per printed page, most would-be buyers will balk at the cost. This, unfortunately, will limit its distribution—especially for students. Despite these relatively minor shortcomings, anyone interested in the biology of herbivorous reptiles would be well served to own a copy (or check one out from their local library), and will likely turn to it often as a valuable source of information.

There can be no question that the European herpetological community is taking their native fauna seriously, for if the British Ordnance Survey is intent on mapping every square meter of Britain, the European herpetological community is dedicated to accounting for the reptiles and amphibians in every plotted square—and beyond. *The Atlas of Amphibians and Reptiles in Europe* is a massive collaborative undertaking, representing the efforts of 95 authors and 14 editors, representing practically the whole of the continent's academic herpetological community, plus the input of a larger contingent of both professional and "non-professional" biologists.

It is easy to examine any book, doomed to being dated even before it is received by the publisher, and find points to negatively critique. This point is merely magnified when one deals with multiple authors and editors. However, I cannot see such important and Herculean efforts disparaged. My only negative comment here shall be minor: more native English-speaking editors were needed. The text is sprinkled with misspellings ("ant" for "and"; "speciesí" for "species' ") and a few quaint challenges to syntax ("…that give an idea of the extraordinary adaptability of the only European reptile strictly arboreal" or "The species inhabits throughout Europe"). I

encountered no phrase that challenged me to interpret the meaning.

What the battalion of authors has presented us is a true atlas, a map depicting the best-guess status of the distribution of every herpetological taxon for a continent. This is not a field guide, and the few pictures are mainly silhouettes, with each account, representative of each family. I would personally liked to have at least a line drawing of each taxon, following the format of the very similar *Atlas de Repartition des Amphibiens et Reptiles de France* (Castanet and Guyetant 1989), but such was not the intent of this atlas. Identification and illustration are still better left to Arnold et al. (1992), Matz and Weber (1983), or Lanka and Vít (1985), though there have been several updates to terminology that still require access to the journals. The present work, however, uses the newest taxonomy, including for example the sheltopusik as *Pseudopus* rather than *Ophisaurus*, and *Macrovipera* for some former *Vipera*.

That said, the *Atlas* is a quintessential set of range maps, accompanied by the latest information on the status and distribution of populations. In fact, this work represents a *sine non qua* for any serious research into either biodiversity or conservation. Non-specialists are given abbreviated synonymies of names most likely to be encountered in earlier literature, and bibliographic sources for systematic, distributional, and general biology of each species. Ecological parameters and environmental influences on each taxon are presented, providing solid groundwork for detailed studies at taxon or population levels. Even herpetoculturists, who would generally avoid works such as the *Atlas*, will find the habitat information extremely useful if they intend to properly care for European species in captivity. Indeed, much of the information for the *Atlas* was collected by "non-professional" herpetologists, to the extent that "many national herpetological associations were born since the onset of the project," ostensibly to help better coordinate the vast data being collected regionally.

The European continent was drawn into grids for this project, giving the compilers the added, and intriguing, ability to relate the percentage of the continent inhabited by each species (given in European style, with a comma instead of a decimal point). Thus, we now know that *Podarcis muralis* occupies 15,00% of Europe, *Rana esculenta* 25,30%, and *Macrovipera schweizeri* a mere 0,02%. Such objective statistics must be of use to conservation policy-makers when deciding about issues pertaining to endangered listings, preservation of critical habitat, and enacting protective legislation.

The *Atlas of Amphibians and Reptiles in Europe* is a splendid book, a rare exception to the generally poor quality of multi-authored tomes. How, I wonder, could a herpetologically active nation like the United States still have no equivalent work? The SEH and its members have provided a wonderful template that other nations (dare I say continents?) would do well to follow. It seems unlikely that any meaningful study of either European herpetofauna or the larger biodiversity issues can credibly proceed without consulting this *Atlas*. The price may set many potential purchasers off; nevertheless, no serious biological library should be without this book. It is a grand testament to the results that can be obtained by concerted and open cooperation among naturalists across borders and professional standings. I hope that the *Atlas* inspires other works of a similar nature to follow for other areas of the globe.

SEA SNAKES
by Harold Heatwole
Orig Ed. 1999
ISBN 1-57524-116-1 172 pp. Paper $24.50
The adaptation of sea snakes to a marine existence is a fascinating chapter in biology. This text describes the varieties and distribution of sea snakes, what they eat and what eats them, how they reproduce and grow, and how they cope with excess salt and scarcity of freshwater. It also discusses how they adjust to diving at depth, enduring long periods without breathing, and describes the nature of their venom and how it functions.

by Dennis King & Brian Green
Orig Ed. 1999
ISBN 1-57524-112-9 134 pp. Paper $22.50
In an easy-to-read style, this book covers the natural history of monitor lizards and includes a description of the world's largest lizard, the Komodo Dragon. This book is an update of the successful 1993 edition, *Goanna*, and contains new information on taxonomy, diet, breeding behavior, and energetics. Two new additions are a chapter on parasites of varanids and a section on foraging strategy.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://falcon.cc.ukans.edu/~gpisani/HRinfo.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 640		$340
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$190

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@sluvca.slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1999 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

2000 — Universidad Autónoma de Baja California Sur, La Paz, BCS, México, 14–20 June 2000 (Carlos Villavicencio, Chair).

About Our Cover: *Hoplocercus spinosus*

South and east of the great basin of the Amazon, the Central Plateau slopes gently across the face of Brazil. Among the distinctive biomes that etch its surface is a region of savannas and twisting gallery forests filled with glabrous, deep-rooted trees with names like *Curatella*, *Piptadenia*, and *Kielmeyeria* (Eiten 1972. Bot. Rev. 38:201–341; UNESCO 1981. Vegetation Map of South America. Explanatory Notes. UNESCO, Paris, 189 pp.). The canopy is low, perhaps 15 meters in height, wrapped around granitic outcrops, and studded with titanium-hard termite mounds. Dry-season fires burn away the dense grass cover brought by the rains. This is Brazil's cerrado. Second only to the Amazon Basin in extent (it covers about 2,000,000 km^2), the cerrado has, until recently, languished while research centered on the Amazon and Brazil's dwindling Atlantic forest (Vanzolini 1963, *In* Simpósio sobre ô Cerrado, Ed. Universidade, São Paulo, pp. 307–321). Perhaps owing to its ragged appearance—cerrado is a mosaic of xeric scrub, buritî palm stands, and open formations—it has been viewed as wasteland, and thus has been destroyed at an alarming rate. In the present decade, over 60% of cerrado has been eradicated or altered seriously. Not only is it fire that sculpts the cerrado, but also ferocious cycles of insolation and irradiation that can encompass as much as 45°C in 24 hours. Permeable soil has provided favorable habitat and much of the region's fauna is fossorial and nocturnal. There are even subterranean trees with only the branches exposed (Cabrera and Willink 1973. Biogeografía de América Latina. OAS, Washington, 120 pp.)!

The lizards depicted on the cover are Brazilian Spinytails, *Hoplocercus spinosus*, a species endemic to cerrado. Much like *Sauromalus* of North America, these lizards retreat into tunnels and inflate the body when threatened. The burrows, usually beneath stones, contain an enlarged terminal chamber. *Hoplocercus* emerge to bask or in the evening to forage; otherwise they tend to remain at the burrow's entrance, with just the spiny tail exposed (Nascimento et al. 1988. Bol. Mus. Pa. Emilio Goeldi, ser. 4:21–66). Spinytails are monotypic, sharing affinities with *Morunasaurus* and *Enyalioides*. Collectively, these genera comprise the Hoplocercidae. They are sexually dimorphic and the banded males display shades of rust and yellow during the breeding season. Spinytails are not known to exceed 150 mm in length, and their diet consists of a variety of arthropods (Carvalho 1949. Publ. Av. Mus. Nac. 5:7–19.). Their distribution, like that of many other cerrado lizards, is patchy (Vitt and Caldwell 1993. J. Herpetol. 27:46–52). They occur in Mato Grosso, Goiás, Maranhão, southern Pará, and Rondônia (Ávila-Pires 1995. Zool. Verh. Leiden 299:1–706; Sick 1951. Natur und Volk 81:30–35.).

The cover is a composite of three photographs, all taken at the Serra da Mesa Hydroelectric Reservoir on the upper rio Tocantins in Goiás, Brazil. The photographer, **Danté Fenolio**, used a Minolta 9xi camera, Fuji Velvia film, and a 100mm Minolta macro lens with flash (lizards), and a 24mm Minolta lens plus natural light (cerrado background). Danté, who is Director of the Amphibia Research Group, will soon begin graduate studies at the University of Oklahoma. He worked in Brazil courtesy of Dr. Nelson daSilva, with financial support provided by FURNAS - Centrais Elétricas S.A. and VBC Energia S.A.

Separation and imaging of Fenolio's photographs is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

SSAR BUSINESS

SSAR Grants-in-Herpetology Committee Annual Report (1999)

An award in the amount of $500 was made to each of the following individuals:

Field Studies.—**W. Bryan Jennings**, University of Texas. Project title: "Ecological morphology of Australian pygopodid lizards."

Laboratory Studies.—**Jonathan Q. Richmond**, San Diego State University. Project title: "Evolution of the *Eumeces skiltonianus* species group (Squamata: Scincidae), with emphasis on the phylogeography of *Eumeces gilberti*."

Conservation.—**Daniel W. Carpenter**, Brigham Young University. Project title: "Conservation genetics and preservation of the endangered Shenendoah salamander (*Plethodon shenandoah*)."

Travel.—**Wendy L. Hodges**, University of Texas. Project title: "Phylogenetic components in the evolution of ecological traits in a unique lizard genus, *Phrynosoma*."

International.—**Irena Grbac**, Croatian Natural History Museum. Project title: "Seasonal variation in thermoregulatory behavior in the lizards *Podarcis muralis* and *Podarcis melisellensis*."

Education.—**Catherine Lynch**, ZooMontana. Project title: "Amphibian surveys for Montana."

1999 Grants-in-Herpetology Committee.—Dawn Wilson, University of Nevada-Reno; Jill Wicknick, John Carroll University; Tod Reeder, San Diego State University; Richard King, Northern Illinois University; Anne Maglia, University of Kansas; David Kizirian, Los Angeles County Museum of Natural History; Michael Dorcas, Davidson College; Peter Ducey, State University of New York at Cortland; Christopher Beachy, Minot State University; Joseph Mendelson III (Chair), Utah State University.

SSAR congratulates the 1999 GIH recipients and thanks the committee members for their efforts.

NEWSNOTES

Upstate Herpetological Association Grants

The Upstate Herpetological Association is now accepting applications for a grant in the amount of US $1,000. This grant is intended to support herpetological conservation, education, or research. All proposals must be received on or before 30 September 1999. The successful applicant will be notified on or about 15 December 1999.

Successful applicants will be expected to submit a report of their work for publication in the Association's newsletter, the *Herp Beat*, and/or give a presentation to either the Albany or Syracuse Chapter of the UHA. Successful applicants are expected to acknowledge UHA's support in any publications that result in whole or in part based on funding by UHA.

Applicants should include the purposes for which the grant is requested, the uses to which the grant will be put, and enough background information on the applicant to enable the reviewers to access the applicant's ability to accomplish the grant objectives. A

letter of reference from a person familiar with the applicant's work in the field is desirable but not mandatory. All applications should include a completion date for the project. All applications should be typed, double spaced, and are not to exceed five pages.

The UHA reserves the right to reduce the grant, divide the grant between two or more individuals, or make the grant to an organization as a whole. All proposals will be considered, but preference will be given to original research, New York herpetology, and captive husbandry and propagation of reptiles. Applicants need not be members of UHA.

Questions and applications should be directed to: *Upstate Herpetological Association, c/o Robert C. Cunningham, 409 Waldorf Parkway, Syracuse, New York 13224-2241, USA; e-mail: rcunn1@twcny.rr.com; Tel. 315-446-9292.*

Brett Stearns Award for Chelonian Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round-trip transportation and limited per diem expenses—to researchers who wish to visit our collections to support their work in chelonian biology. Preference will be given to graduate students.

Proposals should include a short, one page description of the research project and a budget. In the case of graduate students, a letter of support from the student's faculty advisor is required.

Proposals are due on 15 October 1999; notification will be made by 1 December 1999. Awardees are expected to complete their Academy visit by 15 September 2000. Please call (415) 750-7039 for further information.

Proposals should be sent to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

The CAS chelonian holdings are included in the Department of Herpetology database: www. calacademy.org.

Charles Stearns Grant-in-Aid for Herpetological Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one page—description of the research project, a budget, and a letter of support from the student's faculty advisor.

Proposals are due on 15 October 1999, with notification by 1 December 1999. Grantees are expected to complete their Academy visit by 15 September 2000. Please call (415) 750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

Gopher Tortoise Council Awards

The Gopher Tortoise Council annually presents the J. Larry Landers Student Research Award to the best student research project concerning the biology of the gopher tortoise, *Gopherus polyphemus,* or any other relevant aspect of upland habitat conservation. Recent awards have been given for studies on striped newts and red cockaded woodpeckers. The amount of the award is variable, but has been limited to $1000. A proposal should consist of a maximum of four pages and should include a description of the project, a budget, and a brief resume of the student. Proposals should be sent to: *Bob Herrington, Chair, Research Advisory Committee, Department of Biology, Georgia Southwestern State University, Americus, Georgia 31709, USA.* Deadline for receipt of proposals to be considered for the 1999 award is 31 August 1999.

Literature Support Requested for Colección Boliviana de Fauna

The Colección Boliviana de Fauna (CBF) was established in 1990 under an agreement between the National Museum of Natural History (Bolivia) and the Institute of Ecology of the Universidad Mayor de San Andrés (La Paz, Bolivia). Its main goals are to develop a voucher collection of Bolivian fauna and to promote scientific research in zoology.

Currently, one of the priorities of the Herpetology Division is to improve the research library in order to offer better literature support to researchers and students at local and national levels. The CBF is seeking donations of any reprints, research reports, or other documents pertaining to Bolivian herpetology. Donations should be sent to: *James Aparicio E., Curator, Herpetology Division, Colección Boliviana de Fauna, P.O. Box 8706, La Paz, Bolivia. E-mail: herpeto.cbf@mail.megalink.com.*

Wildlife Links: Request for Proposals

The National Fish and Wildlife Foundation, through a cooperative agreement with the United States Golf Association, requests pre-proposals for projects that address wildlife conservation needs on golf courses. Areas of interest include: analysis of management and design techniques for increasing biodiversity on golf courses; research to determine if certain habitat characteristics result in wildlife corridors or barriers on golf courses; preparation of management guidelines for specific species or species suites; programs to monitor the success of wildlife habitat conservation programs on golf courses; and the effects of golfer and maintenance activities on wildlife. All projects must address issues of direct management concern to the golf industry, and should provide management recommendations applicable on at least a regional basis. In addition, proposals should indicate that golf courses have been contacted and will be formal project partners. Request should not exceed $25,000 per year, yet multi-year funding is possible. Deadline for pre-proposals is 16 July 1999. Applicants will be notified by the end of July if a full proposal is requested. Full proposals will be due by 14 September 1999, with funding available in February of 2000. For pre-proposal guidelines, please visit the National Fish and Wildlife Foundation's website: http://www.nfwf.org/nfwfusga.htm or contact Katie Distler, NFWF, via e-mail: distler@nfwf.org.

MEETINGS

Meetings Calendar

6–10 September 1999—10th Ordinary General Meeting of the Societas Europaea Herpetologica, Natural History Museum of Crete (University of Crete), Irakleio, Crete (Greece). Contact: Natural History Museum of Crete, University of Crete, Knosou Av, 71409, Irakleio, Crete. Tel./fax +30 81 324 366; e-mail: nhmc_vtb@cc.uch.gr.

2–4 October 1999—Australian Herpetological Society, 50th Anniversary Conference on Captive Husbandry and Conservation of Reptiles, Sydney, Australia. Contact: Daniel Holloway (e-mail: ozherps@zip.com.au) or visit the Society's web page (www.ozherps.zipworld.com.au).

5–9 October 1999—The Sixth Annual Conference of the Association of Reptilian and Amphibian Veterninarians, Columbus, Ohio, USA. For conference registration information contact: Wilbur Amand, VMD, PO Box 605, Chester Heights, Pennsylvania 19017, USA; fax: 610-892-4813.

8–11 October 1999—Second Symposium on the Status and Conservation of Florida Turtles, Eckerd College, St. Petersburg, Florida, USA. Contact: Gopher Tortoise Council, c/o George L. Heinrich, 1223 Alhambra Way S., St. Petersburg, Florida 33705-4620, USA; tel. (813) 865-6255; e-mail: highpine@gte.net.

15–18 October 1999—Canadian Amphibian and Reptile Conservation Network/Rèseau Canadien de Conservation des Amphibiens et des Reptiles Annual Meeting, Quèbec City, Quèbec, Canada. *(Refer to detailed information below).*

12–17 December 1999—5th Latin American Congress of Herpetology, University of Uruguay, Montivideo, Uruguay. Abstract deadline 30 June 1999. For registration and information contact: Lic. José A. Langone, Secretario Ejecutivo V CLAH, Museo Nacional de Historia Natural, CC 399, 11000 Montivideo, Uruguay (e-mail: vclah@fcien.edu.uy). Within the U.S. or Canada, contact: Dr. Rafael de Sá, Department of Biology, University of Richmond, Richmond, Virginia 23173, USA (e-mail: rdesa@richmond.edu). Web site: http://zvert.fcien.edu.uy/clh.

International Symposium on Herpetological Education: Call for Papers

As part of the 1999 annual meeting of the Canadian Amphibian and Reptile Conservation Network/Rèseau Canadien de Conservation des Amphibiens et des Reptiles, a full day has been set aside for the symposium: "Perspectives on Herpetological Education and its Relation to Conservation Biology." The CARCNet meeting will be held in Quèbec City, 15–18 October 1999, and the symposium is scheduled for 15 October.

Further information is available from the co-organizers: Stan A. Orchard, Chairman, CARCNet, 1745 Bank Street, Victoria, British Columbia, Canada V8R 4V7; Tel/Fax: 250-595-7556; e-mail: sorchard@islandnet.com; Henry R. Mushinsky, Department of Biology/Center for Urban Ecology, University of South Florida, Tampa, Florida USA, 33620-5150; Tel: 813-974-5218; Fax: 813-974-3263; e-mail: Mushinsk@chuma1.cas.usf.edu.

LEGISLATION & CONSERVATION

This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered amphibians and reptiles and their habitats. Please direct all communications to the section editor, Jeffery Demuth (postal and e-mail addresses on inside front cover).

USA: U.S. Fish and Wildlife Service: Effective May 3, 1999 the flatwoods salamander (*Ambystoma cingulatum*) will be protected as a threatened species under the Endangered Species Act. Flatwoods salamanders occur throughout the southeastern U.S. coastal plain of Florida, Georgia, and South Carolina. The following factors are listed as primary causes for threatened status.

First, habitat alterations from agriculture, urbanization, and silvicultural practices have resulted in loss of approximately 82% of the salamander's historical habitat. The losses of both terrestrial and breeding habitats are the primary cause of decline throughout the species' range. Second, there were inadequate existing regulatory mechanisms to protect critical habitats. No federal protection is currently afforded the necessary non-breeding habitats and only limited protection for breeding sites under the Clean Water Act. State regulations in Georgia and South Carolina prohibit direct take of flatwoods salamanders but do not protect habitat. Third, "other natural or manmade factors affecting its continued existence" include fire management, habitat fragmentation, and pesticide (and herbicide) use. Fire suppression is a contributor to the degradation of remaining longleaf pine forests that are primary habitat for *A. cingulatum*. Habitat fragmentation results in decreased opportunity for recolonization after local extinction and disruption of breeding migration routes. Agricultural chemicals pose a variety of threats via direct absorption through the skin and habitat degradation. Finally, overutilization for commercial, recreational, scientific, or educational purposes is listed as a potential threat.

The determination not to designate critical habitat was made on the basis that publication of breeding localities might lead to increased vulnerability to illegal collecting. The final rule lists several activities that would likely violate the Endangered Species Act by affecting *A. cingulatum* breeding sites and surrounding habitat within 450 meters. Additional information can be located in the *Federal Register* 64(62):15691–15704.

Questions regarding this listing should be directed to: *Linda LaClaire, Jackson Field Office, U.S. Fish and Wildlife Service, 6578 Dogwood View Parkway, Suite A, Jackson, Mississippi 39213, USA. Tel: 601/965-4900 ext. 26, e-mail: linda_laclaire@fws.gov.*

USA: U.S. Geological Service – Biological Resource Division: A new long-term frog and toad monitoring program has been launched by the USGS – BRD. The new program, entitled Frogwatch USA, aspires to engage the public in conservation, while helping to compile information about frog and toad population distributions, population trends at individual wetlands, and yearly calling phenologies. Volunteers and scientists from the United States, including Puerto Rico and the Virgin Islands, can contribute to the Frogwatch USA effort by periodically monitoring a convenient wetland site for the presence of calling frogs and toads. After surveying the wetland, they can directly submit their findings via the Frogwatch USA website: www.mp2-pwrc.usgs.gov/frogwatch/www.mp2-pwrc.usgs.gov/frogwatch/. At the end of each season, results will be posted on the website. Potential participants should visit the website to register and find out more information.

The Frogwatch USA initiative is independent from both the North American Amphibian Monitoring Program (www.mp1-

pwrc.usgs.gov/amphibs.htmlwww.mp1-pwrc.usgs.gov/amphibs.html) and the North American Reporting Center for Amphibian Malformations (www.npwrc.usgs.gov/narcam/). The three programs are all concerned with amphibian monitoring and conservation and are overseen by the USGS – BRD, but each program requires different data collection (see websites).

For more information on Frogwatch USA contact: *Gideon Lachman, Frogwatch Coordinator, Patuxent Wildlife Research Center, USGS-BRD, 12100 Beech Forest Road, Laurel, Maryland 20708-4038, USA. Tel: (301) 497-5819, Fax: (301) 497-5784, e-mail: FROGWATCH@usgs.gov.*

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Anne Maglia or Christopher Sheil; postal and e-mail addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are listed. The Web site address is:

http://www.herplit.com/contents

Herpetofauna as Predators of Killer Flatworm?

The terrestrial flatworm *Bipalium adventitium* was introduced to the United States from Asia earlier this century, and in the last 40 years, it has become widespread in suburban gardens and lawns. It is a fierce predator of earthworms that kills its prey by covering it with digestive enzymes, which turn the earthworm into a pink viscous mass. The invasion of this exotic predator may have severe ecological consequences, particularly if there is no native species that preys upon the flatworm. Because herpetofauna often prey upon soil invertebrates, Ducey et al. examined whether six species of salamanders and two species of snakes would eat *B. adventitium* offered to them in the laboratory. They found that none of the herpetofauna treated the flatworm as a prey item. The authors suggest that a combination of gliding movements, chemosensory clues, and distasteful secretions make the flatworms an unlikely prey item for salamanders and snakes.

Ducey, P. K., M. Messere, K. Lapoint, and S. Noce. 1999. Lumbricid prey and potential herpetofaunal predators of the invading terrestrial flatworm *Bipalium adventitum* (Turbellaria: Tricladida: Terricola). Am. Midl. Nat. 141:305–314.

Turtle Densities and Deadwood in Southern River Drainages

Deadwood is an important component in the ecology of river map turtles because they utilize this substrate for basking, foraging, and resting/sleeping. To determine the basking frequencies of five map turtles and the relationship between deadwood abundance and turtle abundance, Lindeman conducted spotting-scope counts of basking turtles in Missisippi, Louisiana, and Kentucky. He found that there was a correlation between low numbers of basking turtles and lack of deadwood in rivers and that some populations, such as *Graptemys flavimaculata* from the Pascagoula drainage, were spotted in much lower densities than expected. Based on these results, he suggests that the practice of "snagging" (the removal of deadwood from river channels) should be limited and that *G. flavimaculata* habitat in the Pascagoula drainage should be protected.

Lindeman, P. V. 1999. Surveys of basking map turtles *Graptemys* spp. in three river drainages and the importance of deadwood abundance. Biol. Conserv. 88:33–42.

Salamanders as Keystone Species in Carolina Ponds

Keystone species are organisms that when removed from a community will result in a decline of species richness. Fauth tested for keystone species in several South Carolina ponds by trapping, dipnetting, and using call censuses. He compared the species diversity of the ponds with the presence/absence of several species and found that, although *Notophthalmus viridescens* and *Siren intermedia* were found to be keystone species in previous studies, there was no evidence of these taxa as keystones in the South Carolina ponds. He did find that *Ambystoma talpoideum* was a keystone species. He concludes that the identity of keystone species varies regionally and with pond characteristics, and several species may be functional equivalents in the role of keystone species.

Fauth, J. E. 1999. Identifying potential keystone species from field data—an example from temporary ponds. Ecology Letters 2:36–43.

Neural Bones Distinct in Indian Ocean Giant Tortoises

The carapase of turtles is made up of several dermal bones; of these, the neural bones, which lie over top of the vertebral column, are the most structurally significant. In an investigation of the neural bones of six species of *Dipsochelys*, Gerlach found that the anterior neurals (I–V) vary less in structure than the posterior neurals and that the different species of *Dipsochelys* can be identified by particular arrangements of these bones. He suggests the arrangement of neurals relates to carapace shape (e.g., domed, flattened) and the structures associated with functional stability in these taxa.

Gerlach, J. 1999. Distinctive neural bones in *Dipsochelys* giant tortoises: Structural and taxonomic characters. J. Morphol. 240:33–38.

Dwarf Chameleon Morphology: Evidence for Species Validity

The taxonomic status of the dwarf chameleons (*Brookesia*) of Madagascar has been the subject of several recent studies, many of which have questioned the validity of several species. Because it had been suggested that *B. tuberculata* and *B. peyrierasi* are synonyms of *B. minima,* Glaw et al. examined the external morphology, particularly the hemipenial structure, of these three taxa. They found several morphologies that differ among the taxa and suggest that each should be considered a distinct species. The authors also discuss several biogeographic considerations for these taxa.

GLAW, F., M. VENCES, T. ZIEGLER, W. BÖHME, AND J. KÖHLER. 1999. Specific distinctness and biogeography of the dwarf chameleons *Brookesia minima, B. peyrierasi* and *B. tuberculata* (Reptilia: Chamaeleonidae): Evidence from hemipenial and external morphology. J. Zool. Lond. 247:225–238.

Mass Amphibian Mortality Linked to Fungus?

Global interest in the decline of amphibian populations has sparked numerous studies geared toward identifying factors responsible for reduction in population numbers. Of particular concern are unhealthy populations that are located in protected areas, because factors causing their decline may be global in nature. Lips monitored a community of amphibians from the Reserva Forestal Fortuna, a protected forest in western Panamá. Through surveys of terrestrial amphibians conducted over a four-year period, she found declines in the number and diversity of amphibians in the area. While conducting stream surveys, she found numerous dead or dying frogs, all of which had high levels of a fungal infection. She also found that a high percentage of tadpoles living in these streams had severe developmental abnormalities. She suggests that the severe population declines of amphibians in western Panamá (and potentially around the world) are caused proximally by a highly contagious fungal infection, but that there are most likely environmental factors working in synergy to precipitate the mortality.

LIPS, K. R. 1999. Mass mortality and population declines of anurans at an upland site in western Panama. Conserv. Biol. 13:117–125.

OBITUARIES

Biographical Sketch of Miguel Alvarez del Toro (Don Miguel): 1917–1996

OSCAR A. FLORES-VILLELA
Museo de Zoología, Facultad de Ciencias, UNAM
Apartado Postal 70-399, México, D.F. 04510, México
e-mail: ofv@hp.fciencias.unam.mx

and

WENDY L. HODGES
Department of Zoology, University of Texas at Austin
Austin, Texas 78712, USA

The herpetological community primarily associates the name Miguel Alvarez del Toro with the famous book "Los Reptiles de Chiapas" published in three editions (1960, 1972, and 1982), and with the zoological park of Tuxtla Gutiérrez, Chiapas, now known as ZOOMAT "Zoológico Regional Miguel Alvarez del Toro," in his honor. But "Don Miguel," as he was known to most of us who had the honor to meet him, was also dedicated to the endless battle of conservation of the wilderness of Chiapas.

Miguel Alvarez del Toro was born in the city of Colima, capital city of the state with the same name, on August 23, 1917. He was an avid collector and observer during his childhood in Colima. In 1932, his family moved to Mexico City where he finished high school and later got his first jobs in natural history. Although his formal education ended at the high school level, his self-taught natural and zoological expertise later earned him honorary doctorates from the Universidad de Chapingo (1992) and the Universidad Autónoma de Chiapas (1993).

At the age of 21, Don Miguel collected birds for the Academy of Natural Sciences of Philadelphia from areas surrounding Mexico City. From 1939 to 1940 he was a taxidermist ("Técnico preparador") for the "Museo de Flora y Fauna, dependiente del Departamento Autónomo Forestal y de Caza y Pesca" in Mexico City. He became subdirector of the same museum in 1940 and remained there until 1941.

In 1942, he moved to Chiapas and accepted the position "Zoólogo General" of the "Departmento de Viveros Tropicales y Museo de Historia Natural," currently known as the "Instituto de Historia Natural." He was appointed director two years later after the premature death of the former director, and he remained in that position until his death in 1996.

Although Alvarez del Toro began as an ornithologist, his expertise extended into other fields of zoology such as mammalogy, arachnology, and herpetology. He was also a pioneer of conservation biology, and his reputation in this field earned him worldwide recognition. He received the Alfonso L. Herrera medal for merit in ecology and conservation (1985), the Paul Getty award for conservation of nature (1989), membership on the UNEP honor roll for

environmental achievement (1992), the national forestry and wildlife merit prize from the secretary of agriculture and water resources of México (1993), and the national merit prize in ecology from the secretary of ecology and social development of México (1994), among numerous other recognitions and achievements.

Don Miguel was a prolific writer, writing for the layman as well as for the scientific community. His literary works include nine books, over 70 scientific and popular publications, and countless newspaper articles. His contributions to the herpetological literature include 15 scientific manuscripts (see Appendix 1) and three books, "Los Animales Silvestres de Chiapas" (1952), "Los Reptiles de Chiapas" (1960, 1972, and 1982), and "Los Crocodylia de México" (1974). In 1985, he wrote his memoirs, "¡Asi era Chiapas!"

In recognition of his work, six species and four subspecies bear his name:

Diaethria mixteca alvarezi (Insecta)
Dismorphia crisia alvarezi (Insecta)
Pulex alvarezi (Insecta)
Troglopedetes toroi (Insecta)
Piranga bidentata alvarezi (Aves)
Anolis alvarezdeltoroi (Reptilia)
Coniophanes alvarezi (Reptilia)
Lepidophyma alvarezi (Reptilia)
Heloderma horridum alvarezi (Reptilia)
Nototriton alvarezdeltoroi (Reptilia)

Probably his most important work was "Los Reptiles de Chiapas," a book published in three editions (a fourth edition has been in press for several years). This may be the most important work in herpetology ever published by a Mexican national and has been the standard reference on reptiles of southern México. It contains numerous observations on the natural history of species inhabiting Chiapas, the majority of them original. This book stands as a testament to his skillful and detailed observations in the field.

Alvarez del Toro also published "Los Crocodylia de México," the product of his efforts and careful studies to preserve the crocodilian fauna of México. This project was funded by the WWF and CONACyT (Consejo Nacional de Ciencia y Tecnología), and was partially conducted at the zoo in Tuxtla Gutiérrez.

The zoo at Tuxtla Gutiérrez was another example of his dedication to nature, conservation, and education. He was the director of the zoo for 52 years. His objective was to teach people about their immediate surroundings, instilling a sense of pride and value in nature that would prompt them to actively support conservation in Chiapas. In 1980, the zoo was moved to a new location, "El Zapotal," a tropical forest very close to Tuxtla Gutiérrez. In this environment, he created a zoo unique among all zoos in the world by exhibiting only native animals of Chiapas, both vertebrates and invertebrates.

Don Miguel was instrumental in the design of a system of protected areas in Chiapas, some of which are now managed by the Instituto de Historia Natural. His desire was to preserve at least a sample of all the natural habitats of the state. Thanks to his efforts, Chiapas has more protected zones with the highest cumulative protected area than any other state in México.

For all of us who had the pleasure to know Don Miguel, he was a leading figure, an example to follow, and in many respects a true mentor. When he died at the age of 79 on the second of August, 1996, in Chiapas, the world lost a superb naturalist, a great conservationist, and a generous human being. His last desire was that his ashes be dispersed in La Selva del Ocote.

Acknowledgments.—We extend our appreciation to Becky and Hebe Alvarez Rincon for providing information about their father. Alfredo Cuaron and Aldolfo Navarro sent proofs of their articles. We thank Kraig Adler for providing the photograph of Don Miguel.

Joseph Randle Bailey
1913–1998

ROGER CONANT
Department of Biology, University of New Mexico
Albuquerque, New Mexico 87131, USA

The death on September 18, 1998, of Joseph Randle "Joe" Bailey ended the career of a distinguished scholar and naturalist who published on all five of the principal groups of vertebrates. His major interest, however, was herpetology, a subject he pursued chiefly in North Carolina and Brazil.

Joe was born September 17, 1913, in Fairmont, West Virginia. His father's name was the same as his, his mother was Elizabeth Weston Maclaren. There was another son, Reeve Maclaren Bailey, who was two years older than Joe. The elder Joseph was killed in 1915, and Joe's mother raised the two boys at Perrysburg, Ohio, but later moved to Toledo where high school facilities were available. Both young men moved on to and graduated from the University of Michigan with Bachelor's degrees.

Joseph R. Bailey, Ann Arbor, Michigan, 1940. Photograph courtesy of Kraig Adler.

Joe's early interest in ornithology was diverted in large part to herpetology by Helen T. Gaige who was in charge of the Division of Amphibians and Reptiles at the University's Museum of Zoology. In the spring of 1936, Joe met Emmett Reid Dunn when the American Society of Ichthyologists and Herpetologists met in Ann Arbor. Dunn, in appreciation of Joe's interest and enthusiasm, invited him to pursue a Master's degree at Haverford College, for which Joe received a fellowship. Under Dunn's influence, Joe became interested in plethodontid salamanders on which he later published, and he co-authored a paper with Dunn on snakes of the Canal Zone and Darien.

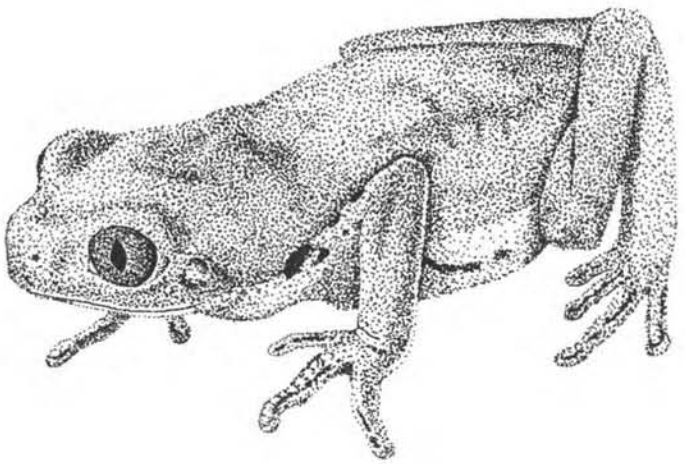
After receiving his Master's, Joe returned to the University of Michigan, from which he received his Ph.D. in 1940. During the summers, in collaboration with James A. Oliver, he worked in New Hampshire on a survey of the Connecticut River Watershed, and they published reports on the amphibians and reptiles and on the fishes in two separate contributions.

Joe then decided he would like to work on snakes of the Neotropics, and he was successful in obtaining an International Exchange Fellowship to Brazil for the period of 1940–1942, the first of four sponsored sessions of work in the largest country in South America. He quickly absorbed Portuguese. Successively, he became a Guggenheim Memorial Foundation Fellow (1953–1954), a Fulbright Lecturer (1961) at the University of São Paulo where he was required to address classes in Portuguese, and a Duke Endowment Grant to South America (1966). He published several papers on Brazilian herpetology alone or with Antenor de Carvalho.

The entrance of the United States into World War II occurred while Joe was in Brazil. He asked the American Embassy what he should do, and he was told to continue his work. When he returned to the States in 1942, he was drafted into the Army Air Corps and was promptly sent back to Brazil, probably because of his familiarity with the language. He remained for a year as a member of a photo mapping squadron. After attending Officers Training School in Georgia, he was dispatched to Hawaii where he was stationed as an Aviation Physiologist until he received he discharge in June, 1946.

Joe returned to Ann Arbor to work at the University Museum. There he met Dorothy "Mike" O'Donnell, who had both a Bachelor's and Master's from Michigan. She was a skilled cartographer and illustrator. She and Joe were married on September 7, 1946, and they became a pair-bonded and inseparable couple. She never became as fluent in Portuguese as her husband, but their daughter, Patricia, even yet visits Brazil frequently in a professional capacity. A son, Robert "Mickey," is in business in North Carolina.

Joe applied for a faculty position at Duke University about the time of his marriage. He was successful, and the Baileys moved to Durham, North Carolina, which became their permanent home. Foreign travel was not over yet, however. He made his later trips to Brazil and, during 1970–1971, Joe was a Senior Scholar (Fulbright) Visiting Professor at James Cook University in Australia. Joe became a full professor at Duke in 1965 and continued in that position until he retired in 1983. He was Curator of the vertebrate collections for 20 years. He worked extensively on the wildlife of North Carolina, and for two summers he was the leader of groups that surveyed the fishes of the mountains.



He was active in several organizations. Among them he served as president of the ASIH in 1972 and president of the southeastern division of the same organization in 1958–1959. He was also vice-president of the Highlands Biological Station during 1976–1978.

After retirement Joe kept an office and laboratory at Duke to continue his studies on South American snakes and the herpetology of his home state. He was one of a many-authored team that produced a popular work on the "Amphibians and Reptiles of the Carolinas and Virginia." His career was cut short by a debilitating stroke on November 1, 1995, that he had to endure until his death in 1998.

Joseph R. Bailey and his brother, Reeve, were the first friends I made when I, as a callow youth of 19, took my first professional job as Curator of Reptiles at the Toledo Zoo. We saw each other frequently, and they often accompanied me on field trips to various parts of Ohio as, on my days off, I sought to gather material for my "Reptiles of Ohio."

After I transferred to the Philadelphia Zoo in 1935 and Joe soon went to nearby Haverford College, we saw each other several times. Afterward our meetings were few and intermittent. I had the pleasure of nominating Joe for President of the ASIH. I fear that because of my own research on the water snakes of the Outer Banks, I may have been partially responsible for his selecting Moorehead City, North Carolina, when he served as the local chairman for the 1964 ASIH meeting. I was quite anxious to see Mullet Pond on the nearby Shackleford Banks to which he arranged for overwater transportation for several others and me. None who attended that ASIH meeting will ever forget our headquarters, the Biltmore-Moorehead City Hotel, manned by an inexperienced staff, and during which the ancient structure gradually fell apart in hilarious fashion.

With the death of Joe Bailey, I have lost an esteemed friend and one who had the great respect of his contemporaries.

The Ho Chi Minh Trail used by North Vietnamese and Pathet Lao forces during the Indochinese Conflict (1961–1975) passed through the limestone karst region in east-central Laos (Khammouan Province) that is presently classified as Hin Namno National Biodiversity Conservation Area (NBCA) (Timmins and Khounboline 1996). Aerial bombing of the region during the conflict has left many large craters that today hold water even into the dry season (November–April) (Fig. 1).

Amphibians are known to have colonized a wide variety of human-made sources of water, such as rain and drainage catchments, windmill wells (Burkett and Thompson 1994), rice paddies and their associated concrete ditches (Fujioka and Lane 1997), reservoirs (Boniecki 1996), irrigation canals (Schneider 1997), road-ruts (Adams and Lacki 1993), and ponds at former mine sites (Lacki et al. 1992; Turner and Fowler 1981). D. R. Karns (pers. comm.) found heavy use by both larval and adult salamanders and frogs of crater ponds created by exploded ordnance at a military test site (Jefferson Proving Ground, Indiana, USA). We report here on the use by frogs of the artificial ponds at the bottom of bomb craters formed during wartime in Laos.

Twenty-two craters along a one kilometer stretch of road (17°29.82'N 105°42.41'E to 17°30.09'N 105°42.68'E) slightly west of the Hin Namno NBCA boundary were sampled for presence of amphibians during the dry season in mid-Februrary 1998. The craters were surrounded by secondary growth and scrub, and were within 1 km of large limestone karst formations. Crater ponds were actively searched at night for post-metamorphic frogs. Ten dips were taken with a hand-net at the edge of each pond to standardize detection of amphibian larvae and other aquatic organisms.

FIG. 1. Artificial pond formed by exploded ordnance during the Indochinese Conflict (1961–1975) near the Ho Chi Minh Trail in Khammouan Province, Laos. Photograph by C. M. Francis.

The craters ranged from 20 to 40 m in diameter and from 3 to 5 m in depth, as measured from the surface of the ground. Eleven of the twenty-two craters (50%) contained standing water at the time of sampling. Cracked mud in the bottom of all the dry craters suggested they held water at wetter times of the year. The maximum depth of water in the wet craters ranged from 0.1 to 1.2 m (mean = 0.59, SE = 0.11). The estimated surface area of water in the craters varied from 2 to 250 m^2 (mean = 103.57, SE = 27.91).

No frogs were detected in any of the dry craters. However, larval or adult frogs were detected in all but one of the wet craters (90.9%). Densities of post-metamorphic frogs in the ponds ranged from 0 to 16 (mean = 4.72, SE = 1.43). Larvae were detected in two of the eleven wet craters (18.2%).

Four species of ranid frogs were found in the crater ponds. These were *Hoplobatrachus rugulosa, Rana erythraea, R. limnocharis*, and *Occidozyga martensii*. Additionally, *Bufo melanostictus* and *Microhyla ornata* were found within five meters of four of the wet craters (36.4%), and the larvae collected during sampling belonged to the former species. All of these frog species have wide geographic ranges and are typical of disturbed areas, including agricultural lands and near human habitation.

Many of the wet craters resembled permanent pond communities. Aquatic vegetation grew in nine of the craters (81.8%), sometimes quite densely. The presence of totally aquatic animal species in the ponds suggested that seasonal flooding of the Xe Bang Fai River, located approximately 0.3 km away at the nearest point from the sampling area, at least occasionally reaches these craters. Specifically, three different species of small fish and an eel were observed in seven of the wet craters (63.6%), and prawns in four of the wet craters (36.4%). Aquatic invertebrates including snails, leeches, larval odonates, heteropterans, and coleopterans were also present.

The ponds appeared to be heavily exploited for food by local people, based on the high density of people seen cast-netting the ponds during the day. This includes the collection of frogs, as two local people that were seen cast-netting a bomb crater pond for small fishes had also harvested an adult *Hoplobatrachus rugulosa*. Immigration of frogs and fish during floodings may be preventing the extirpation of these populations in the ponds, although R. Tizard (pers. comm.) reported that the ponds were sometimes stocked with fish by local people. Regardless of the harvesting, the permanence of the artificial ponds formed by exploded ordnance has provided a suitable environment in which at least six species of frogs live or reproduce.

Acknowledgments.—This work was conducted during an amphibian and reptile survey of Hin Namno NBCA, sponsored by the Wildlife Conservation Society Lao Program. We thank C. M. Francis for providing the photograph and to D. R. Karns for unpublished data.

The Australian water dragon, *Physignathus lesueurii* (Gray 1831), is a large acrodontan lizard which occurs in eastern Australia and has been reported from western New Guinea (Fig. 1). The species appears to be absent from eastern New Guinea (Allison 1982). This unusual disjunct distribution has been widely accepted (e.g., Allison 1982, 1996; Cogger, 1995; Harrison 1928; Moody 1980; Welch et al. 1990; Whitaker et al. 1982), and has long been the subject of comment (Covacevich et al. 1990; Harrison 1928).

The existence of *P. lesueurii* in western New Guinea was first reported by de Rooij (1915) and was based on a single specimen in the Rijksmuseum van Natuurlijke Historie in Leiden in the Netherlands (RMNH 5462). The data associated with this specimen show that it was collected from the Arfak Mountains in what is now the Indonesian state of Irian Jaya. However, there have been no further specimens of *P. lesueurii* from New Guinea reported in the literature. All published reports of *P. lesueurii* in New Guinea appear to be based on De Rooij's (1915) account of this single specimen.

We have searched for additional specimens of *Physignathus lesueurii* from New Guinea in the following institutions: Australian Museum (AM); South Australian Museum (SAM); Northern Territory Museum of Arts and Sciences (NTM); Bernice P. Bishop Museum (BPBM); National Museum and Art Gallery of Papua New Guinea (PNGM); University of Papua and New Guinea (UPNG); University of Michigan Museum of Zoology (UMMZ); Field Museum of Natural History (FMNH); Carnegie Museum of Natural History (CM); California Academy of Sciences (CAS-SU and CAS); American Museum of Natural History (AMNH); Smithsonian Museum of Natural History (USNM); University of Illinois Museum of Natural History (UIMNH); Museum of Comparative Zoology (MCZ); Rijksmuseum van Natuurlijke Historie (RMNH). Although these collections contain over 300 additional specimens of the *P. lesueurii*, none was from New Guinea.

The Leiden specimen (RMNH 5462) is correctly identified as *P. lesueurii* (Fig. 2). However, all other specimens collected from New Guinea and identified as *P. lesueurii* (N = 15) were incorrectly assigned to this species. Fourteen of these belonged to the genus *Hypsilurus* (we follow the taxonomy of Moody 1980 after Cogger 1995). The other misidentified specimen (USNM 101095) was a *Hydrosaurus amboinensis* from Idi Falls on the Mamberamo River in the Van Rees Mountains of Irian Jaya.

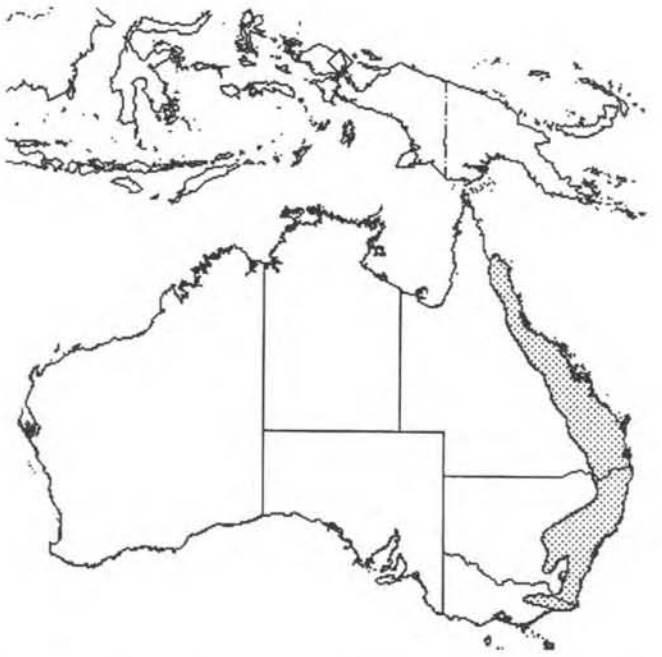

FIG. 1. The reported distribution of *Physignathus lesueurii* in Australia (following Cogger 1995) and New Guinea. The diamond indicates the location from which RMNH 5462 was reputedly collected.

Many museums had specimens of *Lophognathus temporalis* listed as *Physignathus temporalis* (following Worrell 1963; see Cogger et al. 1983 for a full synonymy of *L. temporalis*). This unfortunate artifact of taxonomic history adds confusion to the question of whether *Physignathus lesueurii* occurs in New Guinea. The two species are quite different in external morphology (see photos in Cogger 1995) and are no longer thought to be closely related (Baverstock and Donellan 1990; Cogger and Lindner 1974). The numerous specimens labeled "*Physignathus temporalis*" are not *Physignathus* at all, and provide no evidence for the existence of *P. lesueurii* in New Guinea.

Thus, the Leiden specimen of *Physignathus lesueurii* remains the only evidence we could find that this species occurs in New Guinea. Furthermore the locality data accompanying it may be suspect. RMNH 5462 was purchased from a specimen dealer called "Mulie" in 1871 (Marinus Hoogmoed, pers. comm.), and the locality data associated with the specimen may be incorrect. This specimen may actually have been collected in Australia and mislabeled prior to being purchased by the RMNH.

This issue of the occurrence of *P. leseuerii* in New Guinea is not only of academic interest. The reported occurrence of this species in New Guinea offers an opportunity for the species to be collected in Australia (where it is legally protected) and exported through New Guinea, for the exotic pet trade. This trade, although illegal, is likely of no direct consequence to the conservation status of *P. lesueurii* itself. It is abundant in large areas of eastern Australia (Fig. 1). However, the trade in *P. lesueurii* through Indonesia provides an opportunity for the illicit traffic of other, similar species (e.g., *Hypsilurus* spp. and *Hydrosaurus amboinensis*) whose conservation status is less certain, and which are commonly misidentified as *P. leseuerii*.

FIG. 2. Dorsal view of RMNH 5462. An adult male *Physignathus lesueurii*, reportedly collected in the Arfak Mountains of New Guinea. It was purchased in 1871 from a specimen dealer. The locality data may be in error. (Photograph by Mieke Van Engelen).

In conclusion, we recommend that *Physignathus lesueurii* be considered absent from the herpetofauna of New Guinea until additional specimens are collected. The locality data for the only confirmed specimen (RMNH 5462) reported as coming from New Guinea should be considered suspect as the specimen may have been collected in Australia. *Physignathus leseuerii* is a large, highly visible species. It is unusual that such an organism should not be collected in New Guinea for over a century. It is more likely that the species does not occur there, and that all unvouchered reports are actually of similar-looking species (*Hypsilurus* spp. or *Hydrosaurus amboinensis*).

Acknowledgments.—We thank the curatorial personnel associated with herpetology collections at AMS, SAMA, NTM, BPBM, PNGM, UPNG, UMMZ, FMNH, CM, CAS-SU, CAS, AMNH, USNM, UIMNH, MCZ, and RMNH for cooperation. Marinus S. Hoogmoed provided information about RMNH 5462. Thanks to Aaron M. Bauer for reviewing an earlier draft of the manuscript. This paper was written while GRJ held a Kreitman postdoctoral fellowship in the Department of Life Sciences, Ben Gurion University of the Negev. This is publication no. 264 of the Mitrani Centre for Desert Ecology.

Phrynosoma hernandesi: Correct Spelling

HOBART M. SMITH

Until recently the nominal species *Phrynosoma (Tapaya) hernandesi* Girard (1858:395; *Tapaya* Cuvier was explicitly adopted as a subgenus, as stated p. 394) has always been a name of little significance in herpetology, primarily because it existed throughout most of that time under a cloud of ambiguity. In a few works it was accepted as the name for a valid species, although not after

about 1917 (Stejneger and Barbour 1917). In recent years it has commonly been regarded as an invalid junior synonym of *Agama douglasii* Bell, 1828 (e.g., Hammerson 1986; Stebbins 1985; Zamudio et al. 1997; see Hammerson and Smith 1991, for spelling, often wrongly rendered *douglassii*, another original spelling). At earlier times it was often recognized as a weakly differentiated subspecies of *Phrynosoma douglasi* (e.g., Van Denburgh 1922, and Reeve 1952; the ending with a single *-i* is a permissible variant under the 1999 edition of the International Code of Zoological Nomenclature [hereinafter the "Code"], following the decision of the 1990 meeting of the International Commission on Zoological Nomenclature; see Savage 1990:56).

The mtDNA study by Zamudio et al. (1997), however, elevated Girard's name in both rank and importance by eliminating it from synonymy with *P. douglasi*, which they concluded consists only of the populations in northwestern United States and adjacent Canada that were formerly often regarded as constituting the nominotypical subspecies of the species. Girard's name is the oldest of those applied to the other populations of the species as formerly recognized, in which Zamudio et al. (1997) could find no basis for acceptance of subspecies.

Because Girard's name now appears to be firmly established for a widely distributed and frequently cited species of western United States and adjacent Mexico, the spelling of that name merits attention.

The question of spelling arises because Girard, clearly honoring Francisco Hernández (even though he did not explicitly so state), spelled the new patronym *hernandesi*. He was obviously conscious of Hernández' great work on the biota of Mexico (Hernández 1648), because he cited it in the synonymy of *P. (T.) orbiculare*, to which his description of *hernandesi* referred on the same page.

It is true that in the *P. (T.) orbiculare* synonymy Girard abbreviated all polysyllabic author names ("Bibr., Cuv., Daud., Dum., Gravenh., Grd., Griff., Hernand., Stansb., Wagl., Wiegm."), with one exception (Beechey), spelling in full only that name and those of a single syllable (Gray, Oken, Schinz, Voigt). Girard nevertheless undoubtedly knew the proper spelling of Hernández' name, even though it was not spelled out in full; he was a meticulous worker. That leaves the question of why he spelled the specific name with an "s" instead of a "z".

That the spelling *hernandesi* was a lapsus, even though it was used at least six times in Girard's (1858) thorough review of the entire genus *Phrynosoma*, was apparently immediately concluded by Baird (1859), who was the first to change it to *hernandezi* (he also added an extra terminal *-i*). Van Denburgh (1922:382) noted that Cope (1875), Yarrow (1875, 1883), McLain (1899), and Stone (1911) also used Baird's spelling, as did Smith and Smith (1976, 1993) and, upon the erroneous advice of one of us (HMS), Zamudio et al. (1997). Most others (many dozens) retained Girard's spelling, anchored by the six editions of the North American herpetological checklists beginning with Stejneger and Barbour (1917).

A strong basis for the validity of Baird's spelling is the consistency of spelling of the name Hernández, which is almost as common in Spanish-speaking countries as is Smith in English-speaking ones. For example, the National Union Catalog of Pre-1956 Imprints cites approximately 1000(!) different authors under the name Hernández, and only one under the name Hernandes (the latter appears on an 1870 publication in Paris). Similarly, the 4th, 1976 edition of the Diccionario Porrúa de Historia, Biografía y Geografía de México lists 43 persons under the name Hernández, none under Hernandes. By far the most famous of all, biologically, is of course Francisco Hernández, Mexico's first published naturalist, and still one of its most important and revered ones.

Girard's choice of spelling appears to have been deliberate and a product of a knowledge of classical Latin that was common at that time but is now rare. In classical Latin the letter "z" does not exist, nor do the letters "y" and "w". By consensus, based on commonality of sound or derivation, "s" substitutes for "z", "i" or "j" for "y", and "v" for "w", when the missing letters need to be represented. Therefore the classical Latin letters "i" (or "j"), "s" and "v" represent not only themselves per se, but under certain circumstances the foreign letters "y", "z" and "w", respectively.

On those grounds Girard chose the latinized spelling *P. hernandesi* in honoring Hernandez, and similarly Schmidt chose the spelling *Uta gadovi* to honor Gadow, and Cope *Sceloporus jarrovii* to honor Yarrow. Although it does not superficially so appear, in each case the original spelling actually was retained, but it was expressed by the customary substitute letters.

At least three nominal taxa other than Girard's were named for Hernández between 1831 and 1857: *Chamaeleopsis hernandesii* Wiegmann, 1831 (= *Corytophanes hernandesi*), *Heloderma hernandesii* Wiegmann, 1834 (= *H. h. horridum*), and *Iguana hernandesii* Jan, 1857 (a nomen nudum); in all, "s" appears instead of "z" in the original usage.

All of the examples cited appear to have been created deliberately by choice of their authors, on grounds of latinization. The Code requires maintenance of the original spellings in these cases, including Girard's, because it was obvious that the adopted spelling was deliberate, not a lapsus as required under Arts. 32 and 33 of the Code for correction of an incorrect original spelling. It is true that, at least under the current (1985) Code, eponyms do not necessarily have to be latinized, although they usually were in the past. Thus the spellings *yarrowi*, *gadowi*, *hernandezi*, etc., would be acceptable under the 1985 Code if they were proposed today, but choice of appropriate substitute letters in the past cannot be reversed, under the Code.

It is our conclusion, therefore, that under the Code the correct spelling of the name in question is *P. hernandesi*, the classical Latin equivalent of *P. hernandezi*. It should be noted also that the name *hernandesi* should be pronounced with the accent on the antepenultimate syllable, consistent with the pronunciation of Hernández' name. Written accents on scientific names are not permitted by the Code.

Life History Attributes of a Rare Neotropical Salamander, *Nototriton picadoi* (Plethodontidae: Bolitoglossini)

RICHARD C. BRUCE
Department of Biology, Western Carolina University
Cullowhee, North Carolina 28723, USA
e-mail: bruce@wcu.edu

Nototriton picadoi is a diminutive, arboreal lungless salamander of Costa Rican rain forests. Its taxonomic history is complex; populations currently recognized as *N. picadoi* are known from a few localities at the northwestern end of the Cordillera de Talamanca (Good and Wake 1993). The species is a habitat specialist in moss; most specimens have been taken in clumps of moss on tree trunks and limbs, and moss also serves as nesting sites (Bruce 1998; Good and Wake 1993). These authors noted that egg clutches are unattended by the female parent, as is probably the case in other species of *Nototriton* (Good and Wake 1993; Jockusch and García-París 1998; McCranie and Wilson 1992). This is an unusual feature in plethodontids, where the ancestral condition is female parental attendance at egg clutches (Jockusch and Mahoney 1997).

The current study was undertaken to further define the life history of *Nototriton picadoi*, for comparison with other species of *Nototriton* and other neotropical bolitoglossine salamanders. The field work was conducted in Parque Nacional Tapantí, in the watershed of the Rio Orosi, on the Caribbean slope of the Cordillera de Talamanca, Cartago Province, Costa Rica. Tapantí is an area of premontane rain forest featuring a relatively open canopy with medium to tall trees, dense understory, nearly continuous ground layer, and a profusion of epiphytic bromeliads, orchids, ferns, and mosses (Sawyer and Lindsey 1971). Mosses are especially abundant, often covering extensive areas of the surfaces of trees, shrubs, and lianas. Rainfall is about 3300 mm annually at the official weather station at 1200 m elevation, but exceeds 6000 mm in the higher reaches of the watershed (Coen 1983). Although there is a modest dry season from January through April, rainfall is relatively high (≥ 100 mm) even in the driest month (March). The heavy rainfall and steep slopes result in unstable soil conditions; frequent treefalls create openings that quickly fill with dense tangles of large herbs, vines, and saplings. The lush vegetation and high rainfall would seem to favor large salamander populations, but the several species of *Bolitoglossa, Nototriton*, and *Oedipina* that occur in Tapantí are in fact quite rare (Wake 1987).

I visited Tapantí for periods of several days on each of nine occasions between September 1994 and January 1999, in various months, except for the drier period between mid-January and May. Approximately 270 person-hours were spent searching for *N. picadoi* at Tapantí. Searches were made in daytime, mainly by opening clumps and mats of mosses growing on the ground and on the surfaces of trees, shrubs, and lianas, as high as a person could reach, and occasionally pulling smaller dead trees to the ground to inspect mosses occurring at greater heights. In addition to finding egg clutches, as described herein and elsewhere (Bruce 1998), I located 38 individuals only of *N. picadoi* during the course of the lengthy sampling period. Three were found in moss mats on the ground, and the remaining 35 were taken above ground, to about 2.5 m. All but one of the latter were taken in clumps of moss; the exception was found in the root mass and soil at the base of a bromeliad. Salamanders were found on trunks of trees of various sizes, on horizontal logs, and frequently on small vertical and horizontal branches, and on dead sticks. Several kinds of mosses were used as habitat, but were not identified.

The specimens were preserved by anesthetization in MS-222, fixation in 10% formalin, and eventual transfer to 70% ethyl alcohol. Following preservation, each specimen was measured for snout-vent length (SVL) from the tip of the snout to the posterior end of the cloacal slit to the nearest 0.1 mm. Specimens > 15 mm SVL were then dissected to determine sex and reproductive status. In males, the absence or presence of a mental gland was noted, and the size and condition of the vasa deferentia and testes were determined. Squashes of the vasa deferentia and testes were examined at 100X for the presence of sperm. In females, the diameters and degree of convolution of the oviducts were recorded, the ovaries were examined for the presence of yolked follicles, and the number and sizes of the latter were determined.

Of eight individuals ≤ 15 mm SVL, three (8–10 mm) were similar in size to hatchlings obtained in the laboratory from field-collected egg clutches (Bruce 1998). They were collected in August and January, within the hatching period estimated in the earlier study. Five larger unsexed juveniles (13–15 mm) were collected in June and January. The low frequency of small salamanders in the total sample may reflect the greater difficulty of locating smaller *Nototriton* in the rhizoid tangles of the moss mats.

For males, three individuals 18–22 mm were scored as immature based on the absence of a mental gland, thin and straight vasa deferentia, small testes, and the absence of sperm in the vasa and testes. Ten other males, 20–29 mm, were considered mature. Thus it appears that males mature at 20–22 mm SVL. In mature males the testes were large, white, either club-shaped or elongate, and had prominent ampullae. The vasa were white or gray, with a scattering of brown pigment, and usually showed some degree of

coiling. None of the three smallest mature individuals (20–22 mm), collected in June (1) and August (2), had an obvious mental gland; in each the vasa deferentia were empty, but the posterior ampullae of the testes contained numerous bundles of sperm. I concluded that all three were undergoing spermatogenesis for the first time. In seven larger males (24–29 mm) a mental gland was present, though not prominent, as a darker, shield-shaped area on the throat just behind the lower jaw. Four of these males (26–29 mm), collected in July (1), September (1), and January (2) were in obvious breeding condition, having swollen, coiled vasa deferentia packed with sperm. The other three, taken in September (2) and January (1), had empty vasa. Although these data shed little light on whether males reproduce on a seasonal basis in *N. picadoi*, they do suggest that courtship and mating occur over an extended period of the annual cycle.

Among females, four individuals 17–21 mm were obviously immature, having thin, straight oviducts less than 0.1 mm in diameter, and ovaries with small, whitish, translucent follicles no greater than 0.3 mm diameter. The remaining 13 females, 23–33 mm, were all scored as mature on the basis of having swollen, convoluted oviducts (≥ 0.5 mm) and ovaries with enlarged, yolky follicles. In only two females did the follicles approach the sizes of eggs seen in natural clutches; one such female, 27 mm, collected in mid August, had six yolked follicles enlarged to 1.7–2.3 mm diameter. Her ovarian complement fell within the range of clutch sizes (1–11) observed in the field (see below). In the other individual, the largest in the sample at nearly 33 mm, taken in early January, the 12 yolked follicles were smaller (1.1–1.6 mm), but formed a discrete class separate from the tiny, non-yolked follicles. In other females the yolked follicles were more variable in size, and thus were difficult to assign to the class of follicles destined for the next clutch. However, in none of these females could more than 11 yolked follicles be counted. A number of females had several orange bodies in the ovaries, which presumably represented atretic follicles. These data suggest that females deposit most of their yolked follicles at one time in a single nest, with the remainder undergoing atresia in the ovaries. It is not known whether oviposition occurs on an annual cycle in this species.

TABLE 1. Body sizes of sexually mature *Nototriton picadoi* from Tapantí.

		Snout-vent length (mm)			
Sex	N	Size at maturation	Range	Mean	SD
Male	10	20–22	20.3–29.0	25.3	3.11
Female	13	≈ 23	23.1–32.6	28.3	3.36

The results suggest that females mature at slightly larger sizes, grow to larger sizes, and average larger than males (Table 1). Six of 13 mature females exceeded the largest male in SVL. The difference in mean size between the sexes was marginally significant at $\alpha = 0.05$ ($t = 2.184$, $df = 21$, $P = 0.040$). Thus, the trend is in the direction of female-biased sexual size dimorphism, which is the general pattern in neotropical bolitoglossine salamanders (Bruce 1999).

In the latter part of the field study, additional data on egg laying and nests were collected which supplemented and reinforced earlier observations (Bruce 1998). Two clutches containing late embryos taken on 27 and 28 July 1998 had 4 and 11 eggs, respectively. Both were taken in moss, and in neither case was an attending female present. The clutches were returned to the laboratory, and maintained in the moss in which they were found at temperatures similar to those recorded in the field (≈ 20°C). The four embryos of the first clutch hatched on 13–14 August (SVL: mean = 7.9 mm, SD = 0.24), while 10 of 11 embryos of the second clutch survived, to hatch on 18–20 August (SVL: mean = 7.6 mm, SD = 0.24). On 6 January 1999 I found a cluster of six empty egg capsules of *N. picadoi* in a clump of moss on a stump about 0.5 m above the forest floor. A juvenile (13 mm) was found in moss within 10–15 cm of the egg capsules. These newer data confirm the pattern reported earlier (Bruce 1998) of (1) oviposition, embryonic development, and hatching throughout much of the wet season, (2) the presence of discarded egg capsules in the latter part of the wet season (August–early January), and (3) non-attendance of clutches by the female parent.

Nototriton is one of only three or four genera of plethodontid salamanders in which females do not attend their egg clutches (Jockusch and Mahoney 1997). Within *Nototriton* this behavior is best documented in *N. picadoi* (Bruce 1998). In North American genera where parental care is lacking or reduced, namely in *Batrachoseps* and *Hemidactylium*, the loss of parental care is sometimes associated with communal nesting (Breitenbach 1982; Harris et al. 1995; Jockusch and Mahoney 1997). In *Nototriton* this may also be true of *N. barbouri* in Honduras (McCranie and Wilson 1992). However, there is no evidence of communal nesting in Costa Rican species of *Nototriton* (Good and Wake 1993). In the present study, numbers of yolked ovarian follicles could not be used to reliably estimate clutch size, because most of the few mature females exhibited partial vitellogenesis only. Nevertheless, counts of yolked follicles were similar to numbers observed in field clutches of eggs and in clusters of empty capsules of recently-hatched eggs, as reported herein and earlier (Bruce 1998), indicating that *N. picadoi* probably does not engage in communal nesting.

The data on egg clutches in this and the previous study (Bruce 1998) suggest that oviposition may be seasonal in *N. picadoi*, beginning early in the wet season (May), continuing for several months, followed by hatching of the eggs from August through December. The dissection data on adult females are too limited to either reinforce or refute this conclusion. McDiarmid and Worthington (1970) postulated that in neotropical bolitoglossines, in species living in areas having pronounced wet-dry seasonality, oviposition occurs in the dry season, with hatching following at the start of the wet season several months later; whereas in species occurring in regions lacking a dry season, oviposition may occur in any month. Given the generally wet climate of Tapantí and the brevity of the dry season, it appears that environmental conditions could support year-round reproduction by *N. picadoi* and other salamanders.

Acknowledgments.—I thank Elizabeth Bruce especially for participating in all aspects of the field work. Wayne Van Devender and Steve Mentor also provided valuable help in the field. David Wake was generous in sharing his vast knowledge of *Nototriton* and other neotropical salamanders. The Dirección General de Vida Silvestre, Ministerio del Ambiente y Energia de Costa Rica, issued collecting permits. The staff of the Parque Nacional Tapantí was helpful in facilitating the research. Climatological data were provided by the Instituto Meteorologico Nacional de Costa Rica. I thank the Organización para Estudios Tropicales for assistance in securing collecting permits and for numerous other courtesies. The field studies were supported by grants 5510-95 and 5811-96 from the National Geographic Society and by institutional funds from Western Carolina University.

RECENT POPULATION CHANGES

Conservation Status of the Northern Cricket Frog (*Acris crepitans*) in Colorado and Adjacent Areas at the Northwestern Extent of the Range

GEOFFREY A. HAMMERSON
The Nature Conservancy, 201 Devonshire Street
Boston, Massachusetts 02110, USA
email: ghammerson@aol.com

and

LAUREN J. LIVO
EPO Biology, University of Colorado
Boulder, CO 80309-0334, USA
email: ljlivo@aol.com

The northern cricket frog (*Acris crepitans*) is a small hylid with an historical range extending as far west as eastern New Mexico (Degenhardt et al. 1996) and eastern Colorado (Hammerson 1982). Its presence in Colorado was first documented by Ellis and Henderson (1913), who reported the collection of two juveniles (UCM 195) from the North Fork Republican River drainage at Wray, Yuma County, on 26 October 1912. The next Yuma County record comprised nine individuals collected 3.2 km E Wray on 10 July 1948 (UCM 3235–3243). The known range in that area was enlarged slightly by a specimen collected 8 km E Wray on 9 July 1955 (UCM 10233). A specimen collected in the South Fork Republican River drainage at Bonny Reservoir on 17 May 1958 (UCM 10875) and 12 specimens collected from 3.2 km E Wray on the following day (UCM 10861–10874) provided further documentation of the range in Yuma County. *Acris crepitans* evidently remained fairly widespread in this area through the 1960s, evidenced by a specimen from Wray on 23 July 1965 (KU 98094), two from downstream from Bonny Reservoir, eight from west of Stalker Lake (North Fork Republican River), and two from 8.8 km E Eckley (North Fork Republican River), all collected on 8 October 1967 (KU 125062–125071, 125073–125074).

The 1967 specimens include the last known *A. crepitans* observed from the South Fork Republican River drainage in Colorado. However, the species persisted in the North Fork Republican River in Yuma County through the late 1970s, based on records from our field notes: 4 km E Wray, 10 observed, 7 September 1975; 6.4 km E Wray, 4 June 1977; 5.8 km E Wray, 10 June 1977; 3.2 km W Wray, Stalker Lake, one calling, 18 June 1978; 6.4 km E Wray, five adults observed on 15 July 1979 and 10 adults and juveniles observed on 20 September 1979. A single specimen (UNSM 7792) was collected 4.8 km E Wray on 8 July 1977.

Occurrences in the South Platte River drainage in Colorado are few and questionable. Burnett (1926) reported that a specimen was found at the entrance of a prairie dog burrow near Briggsdale, Weld County, on 27 May 1922; the specimen (number 4843), no longer in existence, was deposited in the collection of the Colorado Agriculture College (now the University of Northern Colorado). This record may be based on a misidentified *Pseudacris triseriata*, which the senior author has observed in exactly the same circumstances in the same area, but Burnett's report included records of *Pseudacris*, suggesting that he was able to distinguish the two species. A record from the southern half of Weld County, mapped by Hammerson (1982), is based on an unpublished species list by an experienced herpetologist, but no documentation of the occurrence is available, and our searches in the area at the time of the report and later yielded no observations of this species. A record of *A. crepitans* from Morgan County (Fitzgerald 1978; Hammerson 1982) is based on specimens we examined in the collection of the University of Northern Colorado in Greeley around 1980. One container included a mixed collection of several *Pseudacris triseriata* with several *Acris crepitans*, plus a label with the data, "Narrows Reservoir site, 21 June 1971." None of the specimens was individually tagged with collection data. One additional specimen in the South Platte River drainage, from Varsity Lake on the University of Colorado campus in Boulder (25 July 1957, UCM 10232), was obtained from a short-lived introduced population that subsequently was extirpated when the lake was drained (T. P. Maslin, pers. comm., 1978; Livo et al. 1998).

Several field surveys by us at the historical localities in Colorado and in other areas of apparently suitable habitat in Yuma County in the 1980s and 1990s (at least one field survey in 10 of 18 years) yielded no additional observations of *A. crepitans*. In Weld and Morgan counties, we made incidental surveys from the late 1970s through 1997. Several searches along Crow Creek near Briggsdale from the 1970s to the 1990s yielded no observations of *A. crepitans*. Recent amphibian surveys in the Pawnee National Grassland (the vicinity of the Briggsdale record), conducted by the Colorado Division of Wildlife, also failed to reveal any extant populations (Ken Kehmeier, Colorado Division of Wildlife, pers. comm.). Our recent surveys along the South Platte River in southern Weld and Morgan counties also yielded no observations of this frog.

Little is known of the current status of *A. crepitans* in other areas in the northwestern portion of its range. In western Nebraska, Lynch (1985) mapped this anuran along the North Fork Republican River contiguous with Colorado. John Iverson collected nine specimens about 30 km east of the Colorado border along the North Fork Re-

publican River near Parks in Dundy County, Nebraska, in 1977 (UNSM 7793–7801), but all other records of *A. crepitans* in the University of Nebraska State Museum from the lower 200 km of the Republican River system in Nebraska are from 1938, 1947, 1973, and 1974. In the South Platte River drainage, Ballinger et al. (1979) found *A. crepitans* no farther west than North Platte, Lincoln County, during their 1975–1978 field surveys. Jones et al. (1981) did not encounter *A. crepitans* at Mormon Island Preserve along the Platte River in central Nebraska but reported that previously the species rarely had been found near that area. Corn et al. (1995) observed a population of *A. crepitans* next to the Niobrara River near Valentine in north-central Nebraska in 1991 (also mapped there by Hudson 1942 and Lynch 1985).

Acris crepitans was common in extreme western Kansas in Wallace County between 1978 and 1980 at about 39°N latitude in 1979 and 1980 when Gorman (1986) collected 91 from three localities. Most KU records for Kansas localities west of 100 degrees longitude are from before 1980. Two individuals were observed at separate localities in Morton County in extreme southwest Kansas in 1978 (Collins and Collins 1991). However, more recent records, each based on single individuals, exist for Greeley (1991, KU 218847), Wichita (1991, KU 218848), and Grant (1992, KU 220758) counties. *Acris crepitans* was observed along the South Fork Republican River in Cheyenne County in 1996 and Smoky Hill River drainage in Sherman County in 1997 (Stan Roth, pers. comm.). This anuran remains common in central and eastern Kansas (Busby and Parmelee 1996; Busby et al. 1996; Collins 1993).

The distribution and status of *A. crepitans* in western Oklahoma are not well known, although *Acris* appears to remain abundant in the central part of the state (J. Caldwell, pers. comm.). Recent vertebrate surveys in the panhandle region of western Oklahoma did not result in any observations of this species (Mark Lomolino, pers. comm.); however, these surveys did not concentrate on amphibian habitats. The only *Acris* records from the Oklahoma panhandle in the Oklahoma Museum of Natural History date from 1933 and are more the 150 km east of the Colorado border.

In summary, *A. crepitans* was fairly common in the Republican River drainage in Colorado through at least the late 1970s, and it may have occurred in the Platte River drainage in Weld and Morgan counties through at least the early 1970s. Subsequent surveys indicate that the species has declined in distribution in Colorado. Conspicuous breeding calls make this species easy to locate, so it is unlikely that the frog still occurs in the recently surveyed locations within the historical range. It is notable that, since 1995, we have observed in Colorado all of the state's other species of amphibians, including species with erratic activity and restricted distributions in the state such as the Great Plains narrowmouth toad (*Gastrophryne olivacea*) and Couch's spadefoot (*Scaphiopus couchii*) and others (e.g., *Bufo boreas* and *Rana pipiens*) that have experienced declines in distribution and abundance in mountainous areas of the state (Corn et al. 1989). In eastern Colorado, suitable habitat for *A. crepitans* exists primarily or exclusively along major streams, and we were able to access these areas by public roads in several locations. Hence existing data indicate that *A. crepitans* is extirpated or extremely localized at best in Colorado. Existing information for the contiguous portions of adjacent states suggests that the species is scarce there as well but extant in at least a few locations in western Kansas.

What accounts for the decline of *A. crepitans* in Colorado? Its continued presence within a few kilometers of the Colorado border in Cheyenne County, Kansas, suggests the possibility of a temporary contraction in the range. Regan (1972) suggested "general aridity, especially in the southwestern part of the study area; wave action around man-made reservoirs; and winterkill due to frost penetration" as potential limiting factors for *A. crepitans* in the western margins of the range. However, we know of no particular climatological events that we can associate with the decline of *Acris* in western Colorado. For example, *A. crepitans* remained common near Wray, Colorado, after the exceptionally cold winter of 1978–1979 when the average temperature in January in northeastern Colorado was 6.8°C below the median—the coldest January during the period 1961–1996 (NOAA-CIRES Climate Diagnostics Center). Exceptional drought conditions did not occur in northeastern Colorado after 1979.

Among anthropogenic factors that may have reduced or eliminated *A. crepitans* populations, habitat change, establishment of exotic species, and chemical contaminants warrant consideration. Over the past two decades some changes in the habitat of *A. crepitans* have occurred in Colorado, such as the lining of some irrigation ditches with concrete, but the extent of primary breeding habitat (ponds with shallow, marshy edges) seems not to have changed much. One Yuma County pond formerly inhabited by *Acris* appeared to have an increased amount of tall, thick vegetation where previously it was open and sunny at the pond edge, but an adequate evaluation of habitat changes in relation to the frog decline is not possible. Land use within the historical range apparently has remained relatively stable in recent decades.

The non-native bullfrog (*Rana catesbeiana*) is a well-known predator on small frogs (Bury and Whelan 1984), including *A. crepitans* (Lewis 1962; Perrill and Magier 1988; Tyler 1978). *Rana catesbeiana* is now abundant within the historical range of *Acris* in Colorado, but it was present at least as early as the 1940s and 1950s (UCM specimens) and may have been abundant in the vicinity of Bonny Reservoir by the early 1950s (Anonymous 1954), so it is difficult to attribute the decline of *A. crepitans* after the 1970s to the impact of *R. catesbeiana*. Also, the two species coexist over much of their ranges in central and eastern North America.

Chemicals associated with agricultural activity in the historical range of *Acris* in Colorado could have caused a decline through excessive mortality in adults and/or embryos, but again lack of sufficient information prevents an adequate evaluation of this possibility. At present, the decline is inexplicable but parallels a similar puzzling decline observed in the Midwest, where the species has largely disappeared from the northern portion of its range in the southern Great Lakes region (e.g., Harding 1997; Jung 1993; Lannoo 1998; Lannoo et al. 1994; Ludwig et al. 1992; Oldham and Campbell 1990; Weller and Green 1997; Vogt 1981). Factors responsible for the decline in the Midwest remain speculative, but the authors just cited mentioned pollution of water by pesticides and/or other chemicals deriving from agricultural sources, vegetation succession, climatic fluctuations (e.g., drought), predation by exotic and native species, and/or competition from other frog species, coupled with the frog's short life span and associated vulnerability to short-term phenomena, as possibly significant. However, further study is needed before any reliable conclusions can be reached on the cause(s) of the decline of *A. crepitans* in the northern and northwestern margins of its range. The species remains common in much of the southcentral and southeastern United States.

Acknowledgments.—We thank Janalee Caldwell, Joseph T. Collins, P. Stephen Corn, Thomas E. Labedz, Mark Lomolino, John D. Lynch, and Stan Roth for providing museum records or information on the occurrence of *A. crepitans* in states adjacent to eastern Colorado. The University of Colorado Museum (UCM), University of Kansas Museum of Natural History (KU), and the Division of Zoology of the University of Nebraska State Museum (UNSM) curate the specimens discussed here. Three anonymous reviewers helped us improve the manuscript.

TECHNIQUES

Laundry Detergent Effectively Preserves Amphibian and Reptile Blood and Tissue for DNA Isolation

Molecular techniques have become invaluable tools in numerous fields of herpetology. The fact that only very small quantities of blood or tissue are needed for these analyses usually allows researchers to continue studies of the live animals after sample collection, and is of special importance if rare or endangered species are involved. Several methods of collecting and storing samples for DNA analysis are currently employed in the field (Dessauer and Hafner 1984; Dessauer et al. 1990). If refrigeration is not possible, blood and tissue samples are usually stored in ethanol, lysis buffers containing sodium dodecyl sulfate, a saturated salt solution, or anticoagulant preservative solution (Arctander 1988).

Using different commercially available laundry detergents (Persil Megaperls®, Persil Supra® Liquid, Frosch®) we previously extracted high molecular weight DNA from several types of tissue (human, lizard, snail, tobacco plant), and obtained a quality and yield of isolated DNA equal to that from conventional DNA isolation methods (Bahl and Pfenninger 1996). The extracted DNA was suitable as template for Polymerase Chain Reaction (PCR) and digestible with restriction enzymes. Furthermore, high molecular weight DNA could be isolated from Wall Lizard (*Podarcis muralis*) tissue after 14 d of incubation (37°C) with the laundry detergent-

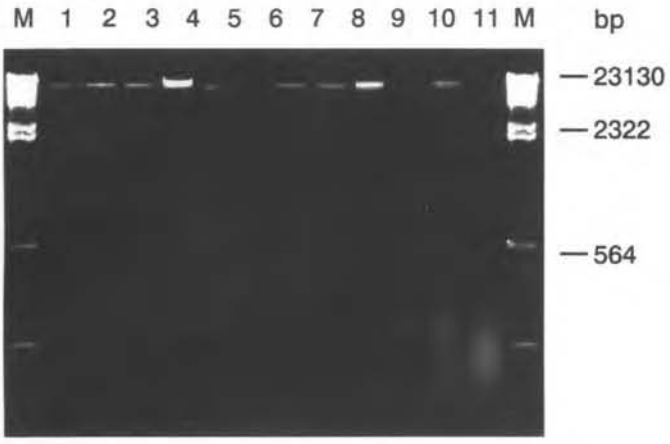

FIG. 1. DNA isolated after different storage procedures. Lane assignment: 1–4, from snake blood after 4 weeks incubation in laundry detergent; 5, from snake blood extracted with laundry detergent after 4 weeks incubation in 90% ethanol; 6–7, from snake tail tip tissue treated with laundry detergent and Hom II buffer, respectively; 8–9, same as 6-7, isolated after 14 d incubation; 10–11, from toad toe-clips extracted with laundry detergent, after 14 d incubation in laundry detergent (10) and 70% ethanol (11); M, l/Hind III marker (MBI Fermentas).

mixture, but not after incubation with a conventionally used DNA extraction buffer (Bahl and Pfenninger 1996). Considering the potential value that this method may have for workers in the field, we were interested to find out whether these results could be reproduced using a wider variety of amphibian and reptile samples, and if the new method could effectively preserve samples collected for DNA analysis and kept at ambient temperatures during field work in a tropical country. Storage of blood and tissue samples in ethanol and a conventional buffer was tested under the same conditions.

Blood samples were taken by cardiac puncture from a euthanized Java Krait, *Bungarus javanicus*. Reptile tissue samples were collected from the tail tip of a captive Many-Banded Krait, *Bungarus m. multicinctus*. This specimen died of multiple parasitoses and sepsis and had been frozen at –20°C immediately after death. Forty-nine millimeters of the total 99 mm tail were cut and nine cross-cut pieces of 42–57 mg were produced. Amphibian toe-clips were obtained from a previously frozen (–20°C) Common Toad, *Bufo b. bufo*.

The conventional DNA extraction buffer herein named Hom II was prepared according to a standard protocol (Sambrook et al. 1989). The commercially available laundry detergent Persil Megaperls® (Henkel Waschmittel KGaA, Düsseldorf, Germany) was suspended to 10% (w/v) in deionized water. Blood samples (0.1–0.5 ml) were transferred to screw top cryovials containing 2 ml of the laundry detergent suspension. Equal blood volumes were stored in 2 ml 90% ethanol. After manually shaking the samples for 30 sec to mix the blood and the laundry detergent suspension, they were kept at ambient temperatures (26–32°C) during four weeks of field work. After this period the samples were frozen at –20°C. Snake tail tissue, in 42–57 mg sections, was transferred to screw top cryovials containing either 2 ml laundry detergent suspension or 2 ml Hom II buffer. Some snake tail tissue samples were frozen immediately at –20°C until DNA isolation, whereas the rest was incubated 14 d at 37°C. Fifty milligrams of amphibian tissue per sample were incubated 14 d at 37°C in 2 ml laundry detergent suspension or 70% ethanol. All fresh tissue (previously frozen in laundry detergent or the conventional buffer) was crude homogenized manually for 30–60 sec with a micropestle 1–2 h before extraction. Twenty microliters proteinase K (10 mg/ml) was then added to the samples to be extracted with Hom II buffer, followed by 2 h incubation at 37°C. Prior to DNA extraction, proteinase K was also added to the samples that had been stored 14 d in Hom II buffer, followed by 12 h incubation at 37°C. To process the ethanol samples the supernatant ethanol was removed and the samples were air dried for 30–60 min at room temperature. Two milliliters laundry detergent suspension or Hom II buffer was added and the samples were processed as above. The DNA was isolated using a standard phenol/chloroform-isoamyl alcohol method (Sambrook et al. 1989). Ethidium bromide fluorescence after gel electrophoresis was used to estimate the integrity and yield of the isolated DNA. The degree of purity of the isolated DNA samples was calculated using the ratio of their spectrophotometric absorptions at 260 and 280 nm, which indicate concentrations of nucleic acids and proteins, respectively.

High molecular weight DNA could be isolated from all samples (Fig. 1, Table 1). No low molecular weight degradation products were observed in DNA samples from snake blood that had been preserved in laundry detergent over a period of four weeks at 26–32°C (Fig. 1, lanes 1–4). All samples preserved in 70% or 90% ethanol contained some degradation products, as did tissue samples under all preservation methods. Fresh snake tail tip tissue yielded more DNA if treated with laundry detergent, but a higher $A_{260/280}$ ratio was achieved by the conventional (Hom II buffer and proteinase K) extraction (Table 1). This might be due to adjuvants contained in the laundry detergent. Incubation of amphibian toe-clips in laundry detergent resulted in fewer degradation products than ethanol storage (Fig. 1, lanes 10–11). No DNA could be detected in the negative controls (extraction from laundry detergent without blood or tissue; data not shown). The DNA isolated from samples which had been incubated (26–37°C) in Persil Megaperls® laundry detergent for two to four weeks was digestible by a restriction enzyme (data not shown), and suitable as a template for PCR (Fig. 2).

Although DNA could be isolated from all samples, differences in quantity and quality were obvious. The best results (high quantity of high molecular weight DNA and no visible amount of degradation products) were obtained from snake blood that had been preserved in laundry detergent. Most commercial washing powders contain a mixture of detergents designed for removal of organic

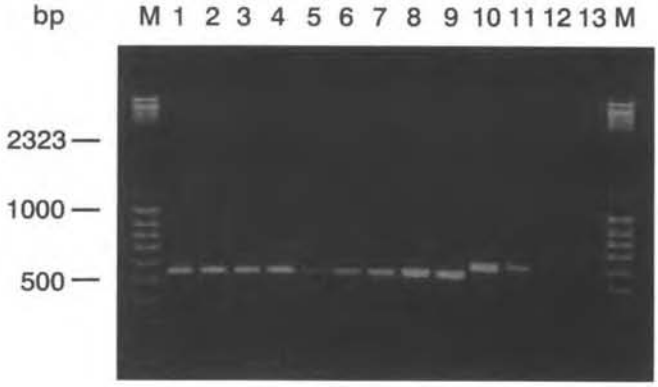

FIG. 2. A 1.4% agarose gel showing PCR amplification products of a 550 base pair fragment of the mitochondrial 16S gene using 3 ng DNA from the samples in Fig. 1. See Fig. 1 for assignment of lanes 1–11, 12–13, water; M, mix of 100 base pair ladder and l/Bst II marker (MBI Fermentas).

TABLE 1. DNA isolation protocols and spectrophotometrically estimated purity and yield.

Species	Material	Incubation	Extraction	Mean DNA Yield ± SD	Range	N	A_{260}/A_{280} Ratio
Bungarus javanicus	Blood	4 weeks, laundry detergent, 26–32°C	Laundry detergent	125 ± 89 µg from 0.1–0.5 ml	43–294 µg	5	1.60–1.87
		4 weeks, 90% ethanol, 26–32°C	Laundry detergent	149 ± 84 µg from 0.1–0.5 ml	65–233 µg	2	1.62–1.81
Bungarus multicinctus	Tail tip	— (fresh)	Laundry detergent	1.3 ± 0.1 µg/mg	1.2–1.4 µg/mg	2	1.38–1.47
		— (fresh)	Hom II buffer	0.5 ± 0.1 µg/mg	0.4-0.6 µg/mg	2	1.80–2.00
		14 d, laundry detergent, 37°C	Laundry detergent	1.1 ± 0.4 µg/mg	0.8-1.5 µg/mg	2	1.31–2.06
		14 d, Hom II buffer, 37°C	Hom II buffer	1.0 ± 0.1 µg/mg	1.0-1.1 µg/mg	2	1.32–1.87
		14 d, 70% ethanol, 37°C	Hom II buffer	0.5 ± 0.3 µg/mg	0.2–0.7 µg/mg	2	1.87–2.50
Bufo bufo	Toe clips	14 d, laundry detergent, 37°C	Laundry detergent	2.7 ± 1.1 µg/mg	1.5–3.8 µg/mg	2	1.41–1.51
		14 d, 70% ethanol, 37°C	Laundry detergent	3.5 ± 0.1 µg/mg	3.5–3.6 µg/mg	2	1.28–1.31

material, enzymes (e.g., proteases, lipases), and chelating complexes (e.g., EDTA), just like most of the conventional buffers for the isolation of genomic DNA. Being a single-cell suspension, blood is quickly and easily digested by the laundry detergent while the digestion of tissue samples appears to be slower. Similarly, passive ethanol diffusion into tissue appears to require more time. Although all tissue preservation techniques we tested yielded amounts of high molecular DNA that are sufficient for analysis, autolytic processes as evinced by DNase activity and resulting degradation products occurred in every tissue sample. Furthermore, the sampling of blood is less harmful for most studied animals than the collection of tissue, and guarantees the availability of undamaged specimens for morphological studies.

In studies of amphibian populations toe-clipping is a frequently used, semi-permanent marking method (ASIH et al. 1987; Donnelly et al. 1994; Ferner 1979). Usually, the toes are discarded after amputation. Gonser and Collura (1996) presented evidence that this tissue is a readily available source of genetic material, and urged that toe-clips should therefore be collected rather than wasted. Our observations on *Bufo bufo* toe-clips confirm their findings, and show that high molecular DNA can be isolated from amphibian tissue by laundry detergent too, even after prolonged incubation at high temperatures.

In a laboratory setting, laundry detergent has proven a rapid and uncomplicated storage method for recovering large quantities of genomic DNA. For applications which require a very high purity an additional extraction with phenol or conventional extraction methods may be needed.

With respect to field work in remote areas, laundry detergent has several advantages over freezing, ethanol, and the conventional buffer systems. Laundry detergent has a low dry weight, can be suspended with clean drinking water, is not flammable, and is not subject to legal restrictions. Unlike many conventional buffer systems, laundry detergent is inexpensive and widely available. Due to these characteristics and its ability to preserve blood and tissue samples under field conditions while providing the first steps of DNA extraction at the same time, it may be of interest not only for laboratory use but especially for herpetologists in the field.

Acknowledgments.—We are grateful to Claudia I. Czimczik for assistance during field work, and to Frank Bambang Yuwono for logistical support in Indonesia. We thank Brian Bowen, Brian I. Crother, Richard A. Seigel, Mary E. White, and an anonymous reviewer for helpful comments and suggestions on the manuscript. Funding of the laboratory work was provided by Henkel Waschmittel KGaA.

A Method to Study the Development of the Dentition in Pleurodont Reptiles

SERGIO R. P. LINE
Department of Morphology
Faculdade de Odontologia de Piracicaba-UNICAMP
13414-018 Piracicaba, São Paulo, Brazil
e-mail: serglin@fop.unicamp.br

Studies regarding the development of the dentition in reptiles are usually performed in decalcified tissue sections (Slavkin et al. 1984; Weill and Tassin 1970; Westergaard and Ferguson 1990). These studies are limited to the observation of few sections in a tooth, and are mainly focused on the cellular aspects of development, as enamel matrix is lost during decalcification procedure. In this paper we describe a simple procedure using scanning electron microscopy (SEM) and histochemistry to study the dentition development in whole mounts of tooth germs.

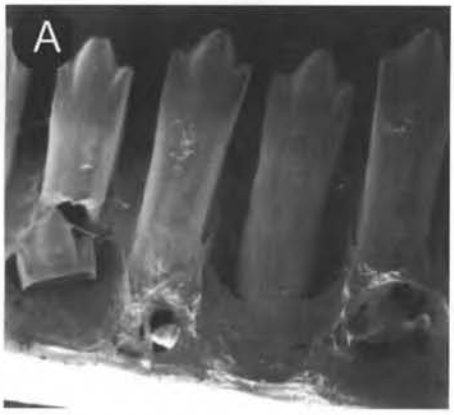

FIG. 1a. SEM image of macerated jaw. Note the presence of three small tooth germs which are inducing the resorption of the functional tooth. X 50.

Three specimens of the iguanid lizard *Tropidurus torquatus* (Vanzolini et al. 1980) were captured and killed by ether inhalation. After decapitation, the heads were macerated for 30 days in a 4% $CaCO_3$ solution at room temperature. After maceration, specimens were boiled in distilled water for 30 min, and the soft tissue was carefully removed under a binocular microscope. To prepare specimens for SEM, tooth germ-bearing bones were air dried and mounted intact on metal stubs. The material was coated with gold using a Balzers MED 010 sputter coater and examined in a Zeiss DSM 900 scanning microscope. For the histochemical analysis, tooth germs were stained with 0.05% Coomassie Brilliant Blue R-250 (Sigma Chemical Corporation, USA) diluted in a 50% methanol, 5% acetic acid solution (Pearse 1985).

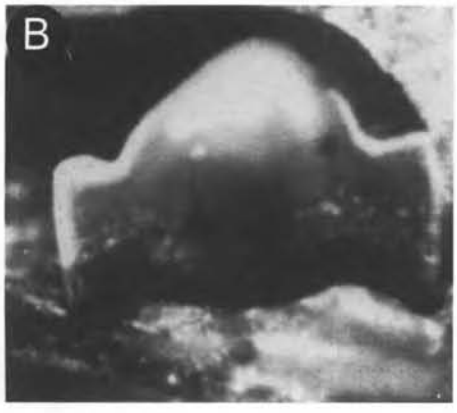

FIG. 1b. Enlarged SEM of a tooth germ. The corrugated surface of the tooth germ reflects large amounts of water loss from the organic matrix (Robinson et al. 1978). Details of the numerous resorption lacunae in the dentin of the functional teeth are also observed. X 140.

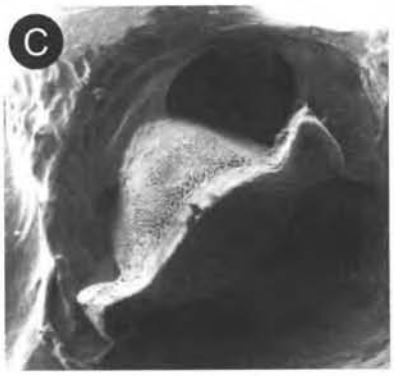

FIG 1c. Coomassie Brilliant Blue staining of a tooth germ. Note that the tip of the tooth germ is not stained, indicating that in this region the organic matrix was already replaced by a mineralized enamel. X 170.

Like in most reptiles, the teeth of the *T. torquatus* are continuously replaced throughout life. This is evidenced by the presence of multiple tooth germs in distinct stages of development (Fig. 1a). This lizard has a pleurodont type of tooth attachment, in which the tooth is attached to the inner margin of the bone jaw (Gaengler and Metzler 1991).

The maceration procedure preserves much of the organic matrix and allows the histochemical staining of the iguanid lizard tooth germs (Fig. 1b). The method described in this paper allows us to directly observe morphological details of odontogenesis (Fig. 1c), as well as the sequence and pattern of tooth formation in pleurodont reptiles and amphibians, and possibly in animals with other type of tooth attachment. This methodology can be used in carcasses of animals that have been dead for several weeks, and is especially useful for the observation of the tooth development in tiny animals, whose tooth germs can have a transverse diameter smaller than 0.1 mm.

Acknowledgment.—Thanks are due to Dr. E. Kitajima from the NAP/MEPA-ESALQ-USP for the use of the scanning electron microscope.

The harmonic radar (Riley et al. 1996, 1998) and harmonic direction finder techniques (Lövei et al. 1997; Mascanzoni and Wallin 1986, Roland et al. 1996; Wallin and Ekbom 1988) provide new possibilities for tracking small animals. The techniques are based on the principle that a tag (diode and antenna) attached to an animal converts incoming radio signals to a harmonic frequency of the original, broadcast wavelength, and re-radiates at this harmonic frequency. Thus, the returned signal differs from reflections from other objects and vegetation, and the tag can be detected. Because the tag does not need a power source, it can be exceedingly small, weighing as little as 0.4 mg (Roland et al. 1996). High-power scanning harmonic radars (which provide information on both the direction and range) are suitable for recording the dynamic trajectories of low-flying animals (particularly insects) over ranges of hundreds of meters, whereas the hand-held harmonic direction finders (which provide information on only direction) are more suited to the location of stationary or slowly moving targets that can be followed on foot.

The harmonic direction finder has been previously used to follow the movements of carabid beetles (Hockmann et al. 1989, Lövei et al. 1997, Mascanzoni and Wallin 1986, Wallin and Ekbom 1988), snails (Lövei et al. 1997), and a variety of flying insects (Roland et. al 1996). We are aware of only one published report on its use on vertebrates. As part of a study of spatial ecology of the Broad-headed Snake, *Hoplocephalus bungaroides*, in Australia, Webb and Shine (1997) augmented their radio-telemetry data by using the harmonic direction finder to follow movements of juvenile snakes with snout-vent length (SVL) < 35 cm. However, they did not specifically address the harmonic direction finder methodology, including its efficacy for use on snakes. The tags we describe are considerable lighter than those used by Webb and Shine (0.004 g versus 0.25-0.41g) and therefore have potential for tracking smaller animals. Here we present our adaptation of the technique for use on the Sharp-tailed Snake, *Contia tenuis*, including tag assembly, tag implantation, and field trials on tracking a small number of snakes. We also discuss problems that we encountered in our field trials. Our hope is that this information will stimulate others into further developing the method for use on vertebrates that are too small for conventional radio-tracking.

Due to the cryptic habits of *C. tenuis*, very little is known of its life history, behavior, and habitat use. In British Columbia, *C. tenuis* is extremely rare and on the provincial Red List of species at risk. Thus, information on its natural history, including movement patterns, is highly desirable for management and conservation purposes. The small size and slender body form of the snakes preclude the use of conventional radio-telemetry (SVL of adults typically < 30 cm, weight < 8 g, body diameter < 0.5 cm).

Tags and their assembly.—For tags, we used a high-frequency Schottky diode (Hewlett-Packard HP5316; detection frequency range: 1 to 26 GHz, capacitance: 0.10pF at 0V, voltage sensitivity: 6.6mV/μW) mounted in the center of a filamentous antenna (Roland et al. 1996). Characteristics necessary for a diode to function with a harmonic direction finder transceiver unit include an ability to operate in the GHz range of frequencies, a high sensitivity to detect weak signals, and a very low noise figure. To increase the strength of the tag suitable for use on snakes, we first soldered the two leads of the diode onto a small (0.1 x 0.4 mm) substrate made of a flexible, printed circuit board material (Kapton™, a polymide-based dielectric film, which is copper-clad and then etched). A copper plate (or lead) is imbedded to each end of the substrate. The substrate provided support for the diode and its fragile gold leads. We then soldered an antenna (0.079 mm or 40 gauge, enameled copper wire) onto each end of the substrate (Fig. 1).

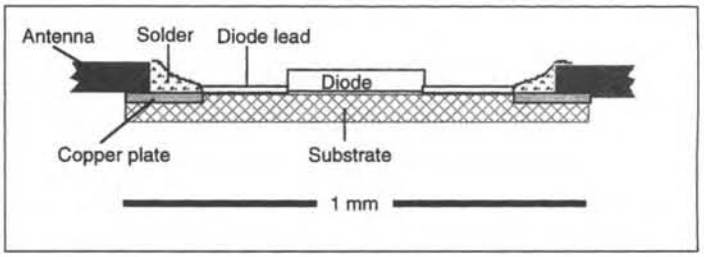

FIG. 1. Diagram of the tag implanted in *Contia tenuis*.

We assembled the tags under a dissecting microscope using a commercially available soldering station (Pace Sensa Temp®) and a 0.4 mm (1/64") diameter soldering bit. As the detection distance increases with antenna length, we used the longest antenna that could be implanted in the snakes (ca. 7 cm in total length). We dipped the tag (diode and antenna) into a presumably inert commercial plastic

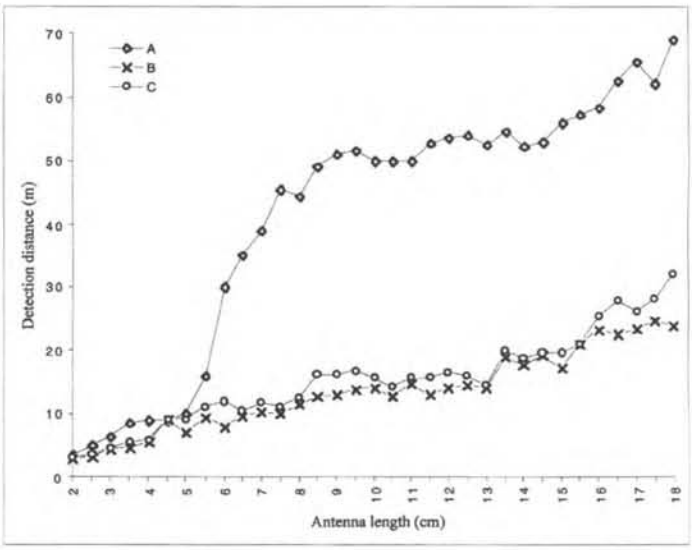

FIG. 2. Maximum detection range of a tag in relation to antenna length. A) Tag 80 cm above ground, transceiver at chest height (100 cm above ground; ◊). B) tag on ground, transceiver at chest height (100 cm above ground; O). C) tag on ground, transceiver above the observer's head (220 cm above ground; X).

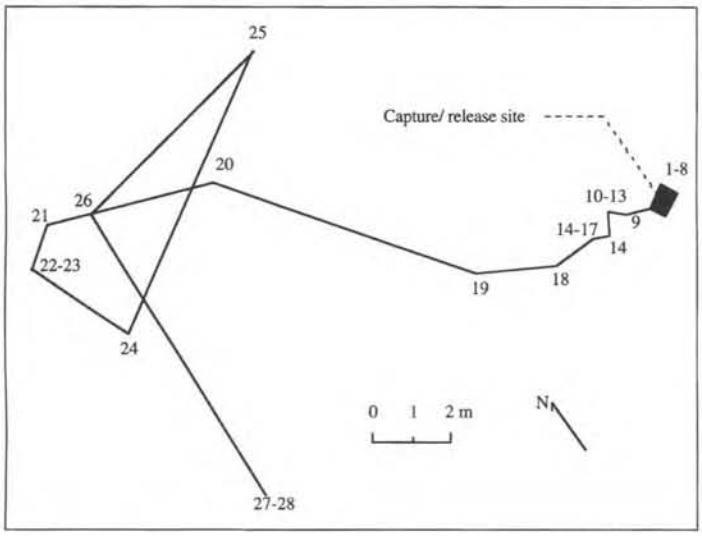

FIG. 3. Movements of an individual *C. tenuis* (# 3) during the night of its release on 11 September 1997. Numbers indicate detection locations.

mixture used for coating tool handles (Plasti Dip®, PDI, Inc. P.O. Box 130, Circle Pines, Minnesota 55014, USA); this potting material has been previously used for coating implanted radio-transmitters used for frogs and snakes (Jansen 1982, Macartney 1985). The total weight of the plastic-coated tag was ca. 4 mg. Webb and Shine (1997) placed tags used for *H. bungaroides* inside flexible, medical-grade silicon tubes.

Detection range.—To determine the relationship between antenna length and detection range, we incrementally shortened an antenna that was initially 18 cm in total length to 2 cm by snipping off 0.5 cm at a time from alternating ends of the tag. After each cut, we measured the maximum detection distance with a portable transceiver unit (RECCO4). The unit transmits a continuous signal at 917 MHz at 4–5 W and receives at 1834 MHz. The incoming wavelengths are translated into an auditory signal to permit tag detection. A Yagi antenna is built into the transceiver unit. We measured the detection distance (A) when the tag was 80 cm above the ground and the transceiver unit was held at chest height (100 cm above the ground), (B) when the tag was on the ground and the transceiver at chest height, and (C) when the tag was on the ground and the transceiver was held above the observer's head (at ca. 220 cm above the ground). In all trials the antenna was horizontal and perpendicular to the line of sight between the tag and transceiver; an antenna end-on to the transceiver cannot be detected (Lövei et al. 1997). We carried out the experiment in an open field where the path between the transceiver and the tag was unobstructed by vegetation.

For antenna lengths greater than 5 cm, the maximum detection distance of a tag raised above the ground was dramatically greater than that of a tag on the ground (Fig. 2). For a tag on the ground, the detection distance decreased steadily with decreasing antenna length. The maximum, unobstructed detection distance of a tag with a 7 cm long antenna, which we used on the snakes, was ca. 12 m when the tag was on the ground. The position of the transceiver unit (at chest height or above the observer's head) had little effect on the detection distance.

Attaching tags to snakes.—Initially, we attempted to attach the tag externally on the dorsum of the snakes by glueing it with SkinBond®, a surgical glue that remains flexible when dry. While tags glued onto four juvenile *Thamnophis ordinoides* (20–25 cm in SVL) remained in place for 7–20 days in captivity, the glue did not adhere properly to *C. tenuis*, presumably due to its smoother, unkeeled scales. Because of the failure of the glue, we decided to attempt subcutaneous attachment. Webb and Shine (1997) implanted tags used on *H. bungaroides* into the body cavity with methods used for radio-transmitter implantation. Our smaller tags allowed subcutaneous implantation.

We first anaesthetized a snake with Metophane® (2% Lidocaine was used for the first two *T. ordinoides*), and then inserted a catheter (11 cm long, gauge 22 [0.85 mm], Monoject® 220, 22 x 3.5) for the length of the tag (7 cm) under the skin. After removing the center rod of the catheter, we inserted a stiff lead wire attached to the tag through the catheter and then slowly removed the catheter while holding onto the lead wire. By pulling the lead wire, we placed the tag in the desired position under the skin. We then removed the lead wire, cut the antenna to appropriate length, and closed the two incisions with SkinBond®.

We implanted tags in four *Contia tenuis* (155–253 mm SVL) and five juvenile *Thamnophis ordinoides* (200–250 mm SVL). Apart from one fatality (the first *T. ordinoides* treated), which probably resulted from holding the snake too tight during the procedure, all snakes recovered and their movements appeared normal 4–6 days after the operation. We kept all four *T. ordinoides* in captivity to investigate signal retention. During the first three months, one *T. ordinoides* died in captivity, apparently from unrelated causes. The remaining three snakes retained functional tags for at least three months. We noted no obvious effects of the tags on feeding, shedding, or growth. We held the four tagged *C. tenuis* in the laboratory for 5–8 days after the procedure to allow for recuperation. We then released the snakes, one at a time, at their original capture locations as part of field trials.

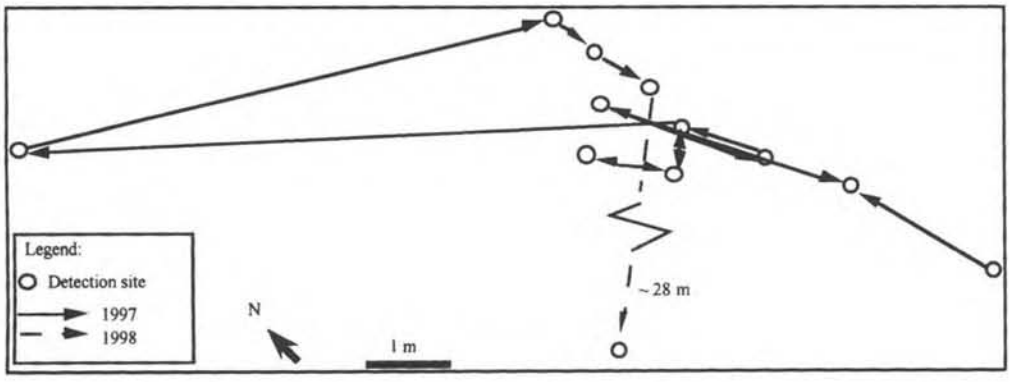

FIG. 4. Movements of an individual *C. tenuis* (# 3) from 12 September 1997 to 20 April 1998. The snake was found a total of 57 times during this period (52 times in fall and 5 times in spring) at the indicated locations. Double-headed arrows indicate movements back and forth between same locations.

Field trials.—We released three *C. tenuis* on North Pender Island (26 August 1997, 11 September 1997, 19 March 1998) and one on Saltspring Island (30 September 1997), British Columbia. The study site on Saltspring was ca. 0.15 ha and that on North Pender ca. 0.75 ha. To examine the feasibility of tracking tagged snakes, we followed the snakes throughout the night of their release, recording locations hourly or more often. For example, Snake #3 (a female) was

released at 1632 h and began to move at 2002 h. We located the snake 28 times during the first night, when it moved a total distance of 44 m (Fig. 3). During each check, we were able to pinpoint the position of the signal to within ca. 15 cm, but only once (at 0219 h) did we visually locate the snake; it traveled mostly under the surface.

After the first night, we were unable to relocate two of the four released snakes. The snakes presumably moved out of the study areas. However, we were able to track the remaining two tagged snakes for several months. From 11 September to 11 November 1997, we located Snake #3 52 times (excluding locations during the first night of release; Fig. 4). The snake spent five days (6 detections) within a log and an adjacent stump, which were in advanced stages of decay. It spent three days (11 detections) under a rock. The remaining 34 detections were at underground locations not associated with surface rocks or logs. During the two-month period, we searched for the snake an additional 17 times without success. In winter, the snake presumably hibernated underground at depths beyond signal detection (i.e., deeper than 20–30 cm). We located this snake again on 21 March 1998, and visually confirmed its identity. We located the snake five times in the same location in the following three weeks using the harmonic direction finder (until 7 April). The distance between two farthest locations was 39 m between September 1997 and April 1998. On 20 October 1998 (about 13 months after tagging), the snake was captured but emitted no signal; most likely, the connection between the antenna and the diode had become detached.

We located Snake #21 three times between 13 March and 20 April 1998 with the harmonic direction finder (excluding locations during the night after its release). One location was under a rock and two were under a downed log. The distance between two farthest captures was 93 m.

The most desirable features of the harmonic direction finder are the small size and relatively long functional life of the tag. In theory, a tagged animal is marked for life, but mechanical wear and tear can shorten tag life, as we documented for one snake. One of our tags lasted at least 208 days in the field, considerably longer than the 8–21 days of battery life for the smallest available radio-transmitters.

Limitations of the technique included short detection range, false signals, and lack of individual recognition. Because the tagged snakes spent most of their time underground, the detection range in the field was < 5 m and often only 1–2 m, a distance considerably shorter than the maximum, unobstructed detection distance of 12 m that we recorded for a tag with a 7 cm long antenna in an open field. Thus, it was necessary to search for snakes by thoroughly scanning the study sites from different directions and with the transceiver close to the ground. The coiling behavior of the snakes and the sigmoidal shape assumed by the antenna of at least one snake, presumably due to muscular activity, probably also contributed to a decrease in the detection distance. A transmitter unit with a stronger, pulsed signal would be desirable, but we are aware of no commercially available sources for such units. Because of its short detection distance, the harmonic direction finder is best suited for detecting relatively short movements. Webb and Shine (1997) obtained movement data for four juvenile *H. bungaroides* in the field. Most movements were < 110 m, but movements up to 250 m were detected.

At our disturbed study sites, various human-made objects, such as metal fencing, concrete with embedded wire mesh, and discarded cans and aluminum wrapping, as well as some iron-bearing rocks, generated false signals (see Lövei et al. 1997 for other sources of false signals). Therefore, before releasing tagged snakes, we examined the study areas with the transceiver and either removed objects emitting false signals or marked them with flags. To identify individual snakes, we tagged only a few snakes per site and verified their identity during visual encounters whenever possible; often, however, digging up the snakes would have resulted in considerable damage to the microhabitats, for example, when the snakes were inside decaying logs. Because known sites with *C. tenuis* are few and restricted in area in British Columbia, the number of individuals that can be potentially tracked without confusion is limited.

Regardless of its short-comings, the field trials showed that the harmonic direction finder can be used to obtain data on movements and habitat use of *C. tenuis*, information that otherwise would not be possible to obtain. With further development of both tags and the transceiver unit, the method holds promise for tracking movements of a variety of small animals.

Costs and permits.—The transceiver unit costs US $6,400 (from RECCO AB, Box 4028, S-181 04 Lidingö, Sweden; e-mail: Recco@recco.se). The diodes cost about US $4.00 each (from Penstock RF/Microwave Distribution Penstock, now AtNet, 520 Mercury Drive, Sunnyvale, California 94086-4060, USA).

Because of its novelty, regulations for the operation of the harmonic direction finder were not well defined in British Columbia at the time of our study and were dealt with on a case by case basis. We suggest that potential users check with their regional regulatory agencies for possible rules and regulations governing the operation of the device.

Criteria for using the harmonic direction finder.—The following questions should be considered before embarking on the use of the harmonic direction finder: (1) Does the target animal move within a relatively small area (e.g., within < 1 ha)? The method is not suitable for detecting long movements. Flying or climbing animals, however, can be detected farther away than animals that are underground or submerged in water. (2) Are there funds available for tag development and assembly? At present, tags are not commercially available and need to be assembled by researchers. Different tag configurations and attachment methods might need to be developed for particular species. (3) Are there objects in the study area that result in false signals? Whereas isolated signal-emitting objects can be identified, widely dispersed contaminants, such as certain metal-bearing rocks, may render the method unsuitable in particular areas. (4) Is individual recognition required? At present, the tags do not allow for individual recognition, and individuals must be identified visually or through other means when located. Passive interrogative transponders (pit tags) might allow individual identification without handling snakes once they have been located using the harmonic direction finder. Alternatively, tracking can be carried out either sequentially or at widely spaced locations.

Acknowledgments.—This work was conducted as part of an ecological study of *Contia tenuis*, for the Ministry of Environment, Lands and Parks, Vancouver Island Regional Office, with funding from Forest Renewal British Columbia. We thank Trudy Chatwin and Susan Holroyd for encouraging us to pursue testing the harmonic direction finder. Malcolm Macartney helped us in developing tag implantation procedures. John Crawford tirelessly assisted us with locating tagged snakes in the field. Sylvia and Kevin O'Reilly, Don Williams, John Crawford, Fred Franke, and Vince and Sandra Knight generously allowed us to track snakes on their properties. We thank Megan O'Shea for sharing ideas on the harmonic direction finder and Joe Riley for his extremely useful comments on an earlier version of this paper. We also thank Daryl Karns, Steve Beaupré, and Howard K. Reinert for their comments that greatly improved this paper.

Venomous snakes present unique husbandry problems to the researcher keeping them in the laboratory. In addition to providing a suitable environment for the snakes, the keepers must ensure the safety of those persons who study and care for the snakes. Researchers may also be required by their institutions to follow established guidelines for animal care and welfare (e.g., UFAW 1987; National Research Council 1996), despite the fact that such guidelines focus mainly on avian and mammalian species and provide little guidance for keeping snakes (Greene et al. 1997). Many institutions are also voluntary members of regulatory bodies, such as the American Association for the Accreditation of Laboratory Animal Care (AAALAC), which carry out compliance inspections. Thus, laboratory caging must meet both safety and animal care requirements. In recent years, the number of commercial cage designs for reptiles has proliferated. These vary from simple, modified aquaria to elaborate polycarbonate (e.g., Plexiglas®) vivaria. However, most of these cages are intended for non-venomous reptiles. Cages designed specifically for housing venomous snakes are generally lacking, so the keeper usually has to modify an existing cage.

In 1993 we began behavioral studies in the laboratory with neonate and juvenile habu (*Trimeresurus flavoviridis*: Crotalinae). Initially, we housed the snakes individually in modified 57 L glass aquaria with sliding, lockable tops, and manipulated the snakes using a standard snake hook. Although our initial research on young snakes was productive (Waters et al. 1996), we found that, as the snakes grew, our caging and method of animal transfer became unsuitable and potentially dangerous. We found that many specimens did not sit on the hook passively, but instead used the hook as a branch, and climbed toward the handler. Efforts to prevent this behavior agitated the snakes and made them difficult to control safely. Therefore we looked for a new cage system that: a) limited the need to handle snakes using a hook, b) provided an environment that reduced stress on the snakes and allowed normal behavior to be observed, c) met the standards for animal care required by AAALAC, and d) maximized the limited space available in our laboratory.

Of the existing caging options we examined, none provided a design that would accommodate all of our needs. Zoos provide examples of well-designed housing for venomous snakes (e.g., Frye 1991, Fig. 2-21). Unfortunately such housing is frequently very large and not easily adapted for laboratory use. Two published accounts describe well-designed cages. Mason et al. (1991) described a cage design for arboreal snakes (specifically *Boiga irregularis*) that met all animal care and welfare requirements. Unfortunately it does not easily accommodate snakes that seek seclusion in a visually isolated retreat. Coote's (1985) design for housing colubrid snakes provided a shelter by using a drawer beneath the main cage. The drawer had a fixed open top making it unsuitable for venomous snakes. In addition, the cage was constructed of wood, which if not completely sealed, does not meet AAALAC guidelines. With these and other designs in mind, we developed a cage that met all of our requirements. We have outlined the design in broad terms, and discuss the features of the design rather than merely providing a blueprint. Interested persons may wish to apply these features when constructing cages for their specific study animal.

Materials.—All elements of the cage are constructed from materials that meet AAALAC guidelines. The main body of the cage is constructed from clear Lexan® polycarbonate panels (6.35 mm thick) and stainless steel hardware. Panels are held together with steel screws. We chose screws, rather than a commercial bonding agent, to facilitate replacement of individual panels if they are damaged. The Lexan® panels tolerate an industrial cage washer that cleans at high temperatures. The hide boxes are not constructed from Lexan® because it was not available in the colors that we wanted. Instead we used acrylic of the same thickness. A complete list of materials is available on request.

Main Cage.—The cage is a 61 x 61 x 40.5 cm box divided into three permanent spaces: a large, upper living space, and two smaller, lower retreats. A hide box is inserted into each of the lower retreats. The living space can be divided into halves by a removable opaque divider (Fig. 1, Element A; Fig. 2). We find this flexibility useful when dealing with different sizes of snakes. Snakes are able to move freely between the living space and hide box via a round, 6.4 cm opening in the floor (Fig. 1, Element G). The openings in the hide box and living space can be independently closed using stainless steel plates that slide under (Fig. 1, Element H) or over (Fig. 1, Element I) the holes, respectively. The plates are secured in place with plastic thumbscrews.

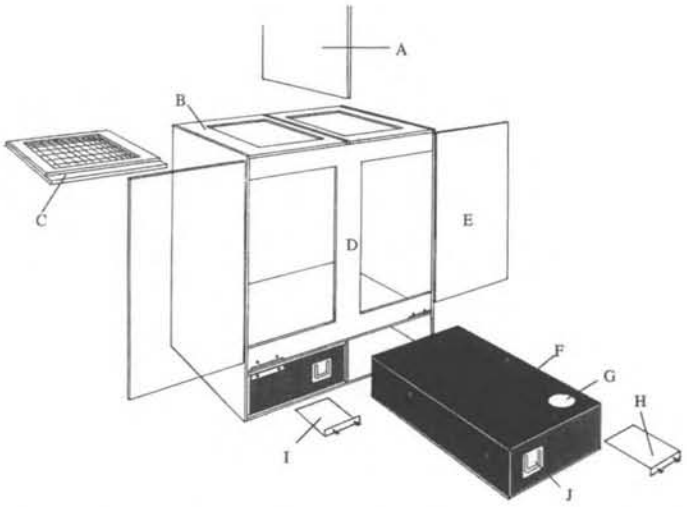

FIG. 1. Schematic diagram of venomous snake cage. A) opaque divider; B) protective top panels; C) lid; D) protective front panel; E) front door; F) hide box; G) opening for snakes to exit box; H) stainless steel sliding plate for hide box; I) stainless steel sliding plate for main cage; J) handle for removing hide box from main cage.

The front of the living space is an **I**-shaped panel (Fig. 1, Element D). This feature serves two purposes: it provides structural support while leaving openings for front access, and it forms a modest vertical barrier (5.1 cm high) to snakes moving forward along the ground. Similarly, the top panels (Fig. 1, Element B) form a lip around the top of the cage to restrict vertical exits when the lids are open.

The front doors (Fig. 1, Element E) are hung with stainless steel piano hinges and close over the **I**-shaped panel. When closed, the doors are secured using padlock hardware that is screwed to the doors and the **I**-shaped panel. In addition, each door has two nylon thumbscrews (top and bottom of distal end of door) that are threaded into the **I**-shaped panel (Fig. 2) to prevent the door from bowing out at the edges.

Each cage lid is constructed from two Lexan® frames with 3.2 mm stainless steel mesh sandwiched between them (Fig. 1, Element C). The mesh ensures adequate ventilation, but can be replaced with a solid panel for those species having high humidity requirements. The cage lids are also hung using stainless steel hinges (Fig. 2). When closed the left and right lids are secured together with a padlock. As with the doors, each lid has two nylon thumb screws which secure the lid to the underlying panel.

Hide Boxes.—The hide boxes are the most important feature of this design because they enable the keeper to avoid direct contact with the snakes. With sliding gates closed, each box may be moved into any other cage and can be weighed with the snake in it.

Each hide box (Fig. 1, Element F) is 39.4 x 58.4 x 8.6 cm. The top, bottom, and sides are constructed of black opaque acrylic to provide a dark retreat. The front and back panels are constructed of dark red transparent acrylic. The red tinted panels provide a measure of visual isolation while permitting the keeper to check the condition and behavior of the snakes in the hide box. An opening (Fig. 1, Element G) allows the snake to exit the hide box and enter the living space. In the face of the front panel there is a recessed handle (Fig. 1, Element J). The rear panel is removable and secured in place with thumbscrews. Snakes readily enter the hide box when disturbed.

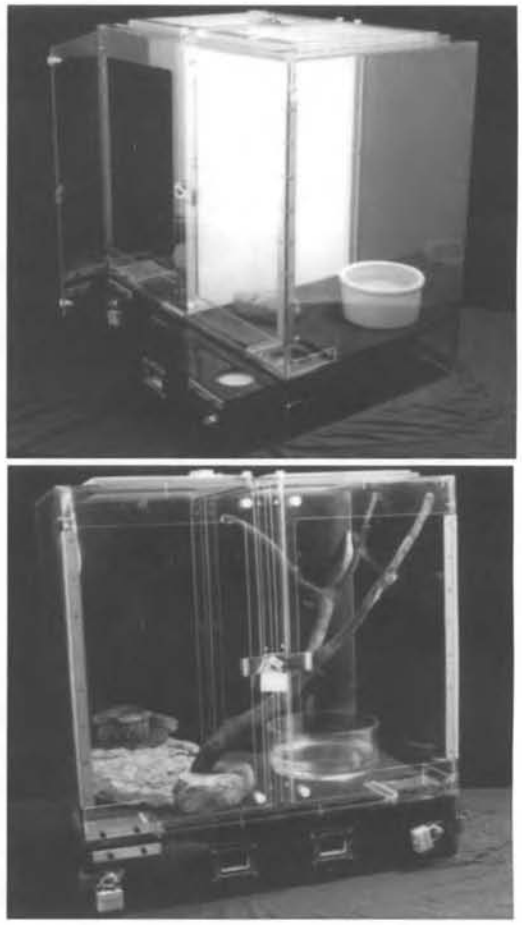

FIG. 2. Photographs of the cage with (a) partition in place; (b) without partition and habu in living space.

We have used this design for three years to house all our venomous snakes (*Trimeresurus flavoviridis, T. elegans*, and *Agkistrodon contortrix*) and have needed to use a snake hook (direct contact) rarely. The hook is occasionally used to encourage snakes to go into their hide box when the living space needs cleaning. If a snake needs to be removed from the hide box, the back panel of the box can be opened and the snake gently lifted out and into the upper living space. We find that the snakes adapt well to the cage and make use of both the living space and hide box. The habu is primarily nocturnal (Koba 1971) and therefore makes greatest use of the living space when the room is dark (Waters et al. 1998). We shifted the light/dark cycle so that the room becomes dark at noon. The mornings can then be used for servicing the cage while the snakes are secured in their hide boxes.

We are in the process of adapting the hide box so veterinarians may use it when treating snakes that become ill. This is usually the only time when the snakes need to be handled directly. One design will incorporate a squeeze box apparatus, while another will be adapted as an induction chamber for anesthesia with inhalation anesthetics.

Acknowledgments.—We thank Dr. M. Nishimura of the Habu section, Okinawa Prefectural Institute of Public Health, Ozato, Okinawa, Japan for his support and providing the habu. We also thank David Pratt and Gary Branson of Biological Services, University of Tennessee, for comments on the design and constructing the cage. We thank Paul Andreadis, Mark Krause, L. Ardell Mitchell, and two anonymous reviewers for comments and suggestions on the manuscript.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 30, Number 1 (March 1999).

CAUDATA

NOTOPHTHALMUS PERSTRIATUS (Striped Newt). **COLORATION**. Occurrence of albinos has been reported for numerous species of salamanders (Dyrkacz 1981. SSAR Herp. Circ. 11. 31 pp.). Here we report observations of four albino striped newts encountered over a three-year period at One Shot Pond, a seasonally-ponded isolated wetland located on the Katharine Ordway Preserve-Carl Swisher Memorial Sanctuary, Putnam Co. Florida, USA. This is the first published account of albinism for *Notophthalmus perstriatus* and apparently the first for the genus *Notophthalmus*.

The first albino observed was a larva captured by dip net on 11 July 1995. This animal lacked normal integumentary pigmentation (Fig. 1) but had a yellowish cast throughout its body. Shiny bluish flecks were present along the dorsal and ventral margins of the tail fin (these appear as white spots in Fig. 1). The eyes appeared to be normally pigmented. Using the terminology of Dyrkacz (*op. cit.*), this animal is described as leucistic with xanthophores. The larva was maintained in captivity until its death on 6 August 1995 at which time it measured 23 mm SVL. We were unable to determine its sex. Although its tail fin and gills had atrophied considerably, it failed to complete metamorphosis. The specimen and a color slide of it in life were deposited in the Florida Museum of Natural History, University of Florida (UF102170). A second larva closely resembling the above was collected by dip net on 17 August 1996 (UF111290, sex unknown, SVL = 21 mm, TL = 43 mm).

FIG. 1. Albino (leucistic with xanthophores) *Notophthalmus perstriatus* larva from One Shot Pond, Putnam Co., Florida. Photo by Barry Mansell.

Two leucistic efts were also captured at One Shot Pond. The first was caught on 8 November 1996 in a bucket trap at a drift fence 60 m from the pond (UF111291, sex unknown, SVL = 20 mm). The second eft (UF 111292, female, SVL = 22 mm, 0.2 g) was captured on 2 December 1997 in a bucket trap on the inside of a drift fence that encircled the pond. Based on the presence of gill buds, it had recently metamorphosed and was moving into the uplands. Both efts lacked integumentary pigmentation although the eyes appeared normal. The stripes, which are characteristic in transformed individuals of *N. perstriatus*, were visible as distinct light lines. Both efts are described as leucistic with xanthophores (Dyrkacz, *op. cit.*).

We have conducted regular sampling in One Shot Pond since July 1995, usually examining about 50 individuals each month. Since October 1996, we individually marked more than 4000 striped newts caught in pitfalls at the drift fence that encircled the pond. We also have observed hundreds of striped newts at numerous breeding ponds throughout the geographic range of the species; however, these four individuals are the only *N. perstriatus* we have encountered with abnormal pigmentation. Additionally, in over 2500 captures at a breeding in north-central Florida, as well as numerous individuals observed throughout the species range in Georgia, USA, Dodd never encountered an albino striped newt (C. K. Dodd, Jr., pers. comm.).

We thank C. Kenneth Dodd, Jr., Richard D. "Bubba" Owen, and Dale A. Johnson for reviewing earlier drafts of this note. Barry Mansell took the photograph in Fig. 1.

PLETHODON DUNNI (Dunn's Salamander). **REPRODUCTION**. Only a single nest of *Plethodon dunni* has been reported (Dumas 1955. Copeia 1955:65). On 27 May 1997, a second nest was discovered at Keel Mountain, Linn County, Oregon, USA (T12N R1E Sec 13). The nest contained an adult coiled around 12 eggs and was located in a cavity in a decay class 5 log (Maser et al. 1979. *In* Thomas (ed.), Wildlife Habitats in Managed Forests: the Blue Mountains of Oregon and Washington, pp. 78–95. USDA For. Serv. Agric. Hndbk. 553.) near the upper surface of the log under loose wood. The log was on a 0.5 m high cut-bank ca. 0.2 m from a small, first-order perennial stream. Habitat at the site was characterized by ca. 40 yr old Douglas fir (*Pseudotsuga menziesii*) and western hemlock (*Tsuga heterophylla*), naturally regenerated after logging, with an understory of sword fern (*Polystichium minutum*), Oregon grape (*Berberis nervosa*), and huckleberry (*Vaccinium parvifolium*). Large decayed downed wood was

abundant due to apparent "high-grading" and/or snag-felling during previous timber management activities; log decay classes 4 and 5 were the most abundant at the site (S. Chan, USFS pers. comm.). A thick layer of bryophytes covered a large portion of the downed wood and forest floor.

Funding was provided to DHO by the USDA Forest Service, National Forest System and the Pacific Northwest Research Station. For assistance in study implementation and coordination, we are grateful to Charley Thompson (Portland, BLM), John Tappeiner (Biological Resources Division, U.S. Geological Survey), and Kerry Murphy (Salem District, BLM).

ANURA

ACRIS CREPITANS (Northern Cricket Frog). **DEATH FEIGNING**. During October 1990, 89 juvenile *Acris crepitans* (20–27 mm SVL) were collected in southwest Normal, Illinois, USA. They were housed in plastic shoeboxes, filled with ca. 1 cm water and tilted to provide an aquatic and terrestrial environment. In captivity, 17 of these frogs displayed death feigning when they were roughly handled or restrained, although this behavior was not displayed as frequently when captured in the wild (pers. obs.). The apparent higher display frequency may be a result of stress levels experienced in captivity, as they were held captive for 2–3 weeks prior to release. When displaying this behavior, a frog would position all limbs in their normal resting position but raised from the substrate so the frog was resting on its venter. The medial digits of the forelimbs were positioned against the tympanum. The hind legs were similarly raised with the femoral portions of the limbs held against the lateral flanks of the abdomen. If released, a frog displaying this behavior would remain in this position for a few seconds, even when turned on its back. Afterwards it would right itself and quickly leap away from the observer. This behavior somewhat resembles the unken reflex displayed by highly toxic frogs such as *Bombina orientalis*. In the unken reflex, a toxic frog will raise its pectoral and pelvic regions from the ground and balance on its ventral surface. In the death feigning behavior, *A. crepitans* only positions its limbs, the pectoral and pelvic regions remain in their usual position, thus causing the chin to rest on the ground as if the frog were crouching. This appears to be the first report of death feigning in *A. crepitans*.

Submitted by **MALCOLM L. McCALLUM**, Department of Biology, Health, and Physical Education, Belleville Area College, 2500 Carlyle Avenue, Belleville, Illinois 62223, USA.

BUFO ALVARIUS (Colorado River Toad). **HABITAT**. *Bufo alvarius* has been reported to occur from elevations of 1250–1387 m in New Mexico (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.). Range-wide elevation has been reported between 0–1610 m (Stebbins 1985. A Field Guide to Western Amphibians and Reptiles. 2nd ed. Houghton Mifflin Co., Boston, Massachusetts. 336 pp.) and 0–1615 m (Cole 1962. Herpetologica 18:172–175; Fouquette 1970. Cat. Am. Amphib. Rept. 93:1–4). Degenhardt et al. (*op. cit.*) described the habitat as "desert shrub characterized by broad flat expanses of creosotebrush and mesquite, in rocky riparian zones grown to cottonwood and sycamore, in muddy stock ponds". Stebbins (*op. cit.*) described range-wide habitat as "arid mesquite-creosotebush lowlands and arid grasslands into the oak-sycamore-walnut groves (plant community) in mountain canyons" and noted that the species "enters tropical thorn forest in Mexico." Fouquette (*op. cit.*) described the occurrence "in desert, but also in grassland and lower oak-woodland" of the Lower and Upper Sonoran life zones. Cole (*op. cit.*) listed 13 specimens collected in San Simon and San Bernardino Valleys as well as a specimen from the Peloncillo Mountains "200 yards E of the Arizona-New Mexico State Line on Geronimo Trail" in "an open meadow surrounded by pine-oak-juniper forest" (R.W. Axtell, pers. comm.). Presently, this site in Cottonwood Canyon is a mosaic of encinal woodland and savanna, with Mexican pinyon (*Pinus cembroides*) and alligator bark juniper (*Juniperus deppeana*) occurring throughout.

During the summers of 1997 and 1998, we observed six *B. alvarius* at elevations above 1685 m in Clanton Draw (NM) of the Peloncillo Mountains. These specimens were found in pine-oak woodlands characterized by high densities of Chihuahua pine (*Pinus leiophylla*), Mexican pinyon, alligator bark juniper, and various oaks (*Quercus* spp.). On 9 August 1998 a single specimen (Arizona State University ASU 30937) was collected at 1763 m in Cottonwood Canyon (NM) on a steep (>30°) rocky slope dominated by native grasses. Our observation of multiple individuals over two years, in addition to Cole's (*op. cit.*) 1961 specimen, indicate an adult population of *B. alvarius* occupies this rugged Madrean community bounded by grasslands and Chihuahuan desert scrub.

BUFO AMERICANUS (American Toad). **DEPTH RECORD**. On 19 June 1997 while SCUBA diving in the Connecticut River we captured two *Bufo americanus* tadpoles at a depth of 8 m. The dive site was near the confluence of Pine Meadow Brook and the Connecticut River, ca. 42°42'34"N, 72°26'14"W in the town of Northfield, Franklin County, Massachusetts, USA. The river bottom dropped steeply to 1 m and then gently to a maximum of 10 m. The bottom was a continuous bed of live mussels overlaying dead mussel shell and fist-sized rocks. The flow regime is variable on a diel basis due to an upstream power plant pumping station, with the current ranging from 0–2.5 knots. The two tadpoles, which had not started to transform, were found at a depth of 8 m while we were turning rocks and shells. We identified the tadpoles as *Bufo* sp. because of their distinctive coloration and size. The species, *B. americanus*, was inferred because the only other toad occurring in the area, *B. woodhousii fowleri*, breeds later in the year (Degraaf and Rudis 1983. Amphibians and Reptiles of New England: Habitats and Natural History. Univ. Massachusetts Press. Amherst. 85 pp.). In 1997, due to a cool and prolonged spring season, local *B. americanus* did not breed until mid-May with *B. woodhousii fowleri* delaying reproduction until June (TFT, pers. obs.). Typically, *B. americanus* breed in ponds and still, shallow water (Klemmens 1993. Amphibians and Reptiles of Connecticut and Adjacent Regions. State Geological and Natural History Survey of Connecticut. Bull. 112 xii+318 pp.). They also breed in local streams and rivers. This is the first report of a toad tadpole in deep and relatively fast flowing water. It is probable that eggs or tadpoles were washed into the river and settled in this vicinity as *B. americanus* have not been reported to breed in the river itself. The shells and rocks provide a still water microhabitat until transformation.

BUFO BOREAS (Boreal Toad). **PREDATION**. Numerous predators of *Bufo boreas* adults and tadpoles have been reported in the literature. In 1994 and 1995, one of us (JPG) examined the stomach contents of 154 brook trout (*Salvelinus fontinalis*) from a boreal toad breeding site containing numerous tadpoles in Chaffee County, Colorado, USA. Most guts contained chironomid pupae and larvae, but none contained any tadpoles. Ten 150-mm greenback cutthroat trout (*Oncorhynchus clarki*) coexisted in a 3.7-m long hatchery trough with eight *B. boreas* tadpoles for 48 days and did not consume or injure any tadpoles. These observations suggest that these salmonids do not routinely consume boreal toad tadpoles.

When offered 200 boreal toad tadpoles, four captive mallards (*Anas platyrhynchos*) consumed the tadpoles in less than one minute. In Chaffee County, mallards have been observed at boreal toad breeding sites apparently consuming tadpoles (C. Fetkavich, pers. comm.). Medium and large odonate larvae consumed boreal toad tadpoles in laboratory trials, but we did not observe predation by odonate larvae at boreal toad breeding sites. We frequently observed spotted sandpipers (*Actitis macularia*) consuming toadlets in the Woods Creek drainage, Clear Creek County. Most predation occurred in August, when the toadlets were metamorphosing. During one observation on 9 August 1995, a spotted sandpiper ate 21 newly metamorphosed toadlets in approximately 30 seconds. Most of the toadlets were on the shore, but a few were in shallow water. At one site where dropping water levels exposed >1 m of unvegetated shore, the sandpipers walked parallel to the shoreline, picking up toadlets as they progressed. Also in August, American robins (*Turdus migratorius*) were observed eating tadpoles from the shallow portions of a boreal toad breeding pool. One robin ate six tadpoles in a one-minute period.

We also observed predation on adult boreal toads by red fox (*Vulpes vulpes*) and raccoon (*Procyon lotor*). Beginning in late June 1998, and continuing through July, raccoon tracks were found at three breeding ponds at or near the stripped-off skins of at least six adult toads, including three toads that had been equipped with radio transmitters. The skins were discarded in shallow water. A toad carcass was found near fox tracks, with no other mammal or bird tracks in the vicinity. In contrast to raccoon predation, the body parts appeared chewed rather than peeled away and were on the ground rather than underwater. In 1998, late June and early July were particularly dry, which may have concentrated both the toads and these mammalian predators, as we observed no such predation in the previous years (1995–1997) at this site. In addition, in 1998 a domestic dog tore the abdomen of an adult female toad, which died from the wound.

Funding for this work was provided by Great Outdoors Colorado through the Colorado Division of Wildlife. We thank Anne Beierle, Environmental Coordinator, and the Climax Molybdenum Company for facilitating research activities. Bud Stiles assisted with the field work.

DENDROBATES AURATUS (Green Poison Frog). **PREDATION**. Predation on members of the genus *Dendrobates* is apparently rare, perhaps due to the presence of highly toxic alkaloids in their skin (Myers and Daly 1983. Sci. Am. 248:120–133). Here, I report observations of predation on *Dendrobates auratus* by the tarantula *Sericopelma rubronitens* on Toboga Island, Panama.

On 5 June 1985, I observed an adult *S. rubronitens* rush out of its burrow, capture a passing female *D. auratus* in its mandibles, and retreat back into its burrow. Apparently this spider was not hungry or was repelled by the frog's toxins as the frog left the burrow after ca. two minutes. The frog left the burrow slowly, hopping at a normal pace. Presumably the tarantula could have retrieved the frog if it had simply escaped. Examination revealed the frog was unscathed except for two parallel scratches in the skin on the right side, apparently from the fangs of the tarantula.

On 20 June 1985, I observed a courting male and female *D. auratus* as they passed by a rock under which a tarantula had a burrow. The spider rushed out, captured the male, and returned into its burrow. After one hour the spider was captured, examined, and found to be clutching the frog in its mandibles The frog was dead although the cause of death was not obvious, and it was not apparent that the tarantula had been attempting to consume the frog.

At a later date, I captured a *D. auratus*, tied a length of fishing line around its waist, and presented it to a foraging tarantula I had observed earlier. The spider immediately grabbed the frog in its mandibles and retreated under a rock. I allowed the spider to remain in this position for 2.5 h and then retrieved the frog. Examination of the corpse revealed two puncture marks in the upper venter, near the left foreleg. The frog's body on the left side was deformed and the internal tissues were dissolved and partially removed. Hence, it appeared the tarantula had injected the frog with digestive fluids and was in the process of removing the liquefied tissues.

The tarantula was kept in a terrarium for two days and showed no obvious ill effects from partially consuming the poison frog. Apparently *S. rubronitens* does prey on *D. auratus*, although the first observation of capture and subsequent release of a female suggests *D. auratus* may not be a preferred prey item.

I thank A. S. Rand and the administrative staff of the Smithsonian Tropical Research Institute for advice and assistance.

GASTROPHRYNE OLIVACEA (Great Plains Narrowmouth Toad). **AGGREGATION WITH TARANTULA**. Blair (Copeia 1936:115) was the first to call attention to the tarantula *Aphonopelma hentzii* sharing its burrows with *Gastrophryne olivacea*, citing that up to nine of the toads were found in an individual burrow. In a presentation at the 1991 SSAR meeting I elaborated on the nature of this association, offering evidence that the tarantulas indeed would not attack *G. olivacea* or *G. carolinensis* but would attack and eat the frog, *Acris crepitans*.

On 14 April 1998 at a site in Wagoner County, Oklahoma, USA, I found several tarantulas under flat stones, some sharing the burrow with toads, others not. Under one stone I found 22 *G. olivacea* with a female tarantula. When uncovered, all of the animals attempted to rush into the burrow, the crush being so great that the animals literally plugged the burrow and could not force their way through the entrance. Because the toads must journey up to several hundred meters to reach their breeding sites, experiments are in progress to determine if individual toads return to the same burrows after the mating season.

LEPTODACTYLUS CHAQUENSIS (NCN). **DIET.** *Leptodactylus chaquensis* is a common frog in the Chacoan region of Argentina, where it is found in the eastern foothills of the Andean system (Jujuy, Salta, and Tucuman) up to the central marshes of Corrientes (Ibera swamps), the Entre Rios, and Santa Fe Province (Cei 1980. Amphibians of Argentina. Monitore Zoologico Italiano (NS). Monogr 2, 609 pp.). Nine individuals were collected during the following periods: April–June 1996 (one male 74.5 mm SVL; two females 52.1 and 52.3 mm SVL), October 1996 (two females 54.4 and 75.8 mm SVL), and January 1997 (two males 68.1 and 47.6mm SVL; two females 61.5 and 64.7 mm SVL). All specimens were collected 15 km northeast of Corrientes (27°28'S, 58°50'W) Corrientes, Argentina. *Leptodactylus chaquensis* is a nocturnal, active forager. Table 1 summarizes data collected during this study.

I thank Arturo I. Kehr for suggestions on field and laboratory methods and for reviewing a draft of this manuscript.

LITHODYTES LINEATUS (Ant Frog). **COLORATION.** The leptodactylid frog *Lithodytes lineatus* occurs in eastern Peru, Ecuador, Colombia, Bolivia, Brazil, southern Venezuela to the Guianas, and on the island of Trinidad (Frost 1985. Amphibian Species of the World. Allen Press, Inc. and Assoc. Systematics Collections. Lawrence, Kansas. v + 732 pp.; Cochran and Goin 1970. Frogs of Colombia. Smithsonian Inst. Press. 655 pp.; Murphy 1997. Amphibians and Reptiles of Trinidad and Tobago. Krieger Publishing, Malabar, Florida. 245 pp.).

Normal coloration for *L. lineatus* consists of a black dorsum and a pair of wide yellow to golden tan dorsolateral stripes extending from the snout to nearly the groin. The dorsal surface of the limbs is black to brown with black or dark brown bars; red spots are present in the groin. The flanks are black and the venter is normally grayish brown (Duellman 1978. The Biology of an Equatorial Herpetofauna. Univ. Kansas Mus. Nat. Hist. Misc. Publ. 65. 352 pp.; Rodriguez and Duellman. 1994. Guide to the Frogs of the Iquitos Region, Amazonian Peru. Univ. Kansas Mus. Nat. Hist. Spec. Publ. 22. 106 pp.).

On 6 July 1998, an aberrant adult *L. lineatus* (ca. 35 mm SVL; Univ. Texas at Arlington (UTA) Slide 24363) was photographed and released in the riparian forest at Quebrada Ungurawe in the vicinity of Monteverde, Rió Tigre, Loreto, Peru (W. Lamar, pers. comm.). The specimen lacked all black pigment and was a uniform pale brown (flesh color by night). The dorsolateral stripes on the back were a weaker yellow, but the red markings in the groin appeared normal. The bars occurring on the dorsal surface of the limbs were yellow, and the ventral surface was pale gray to white.

Hypomelanism has been documented in anurans (Bechtel 1995. Reptile and Amphibian Variants: Colors, Patterns, and Scales. Krieger Publishing, Malabar, Florida. 206 pp.); however, this is the first report of hypomelanism in *L.lineatus*.

Submitted by **MATTHEW J. RUSSELL**, Department of Biology, University of Texas at Arlington, Box 19498, Arlington, Texas 76019, USA.

PHYLLOMEDUSA HYPOCONDRIALIS (NCN). **DIET.** Although many aspects of the ecology of *Phyllomedusa hypocondrialis* were discussed by Cei (1980. Amphibians of Argentina. Monitore Zoologico Italiano (NS). Monogr. 2, 609 pp.), the diet has not been investigated. Nine individuals were collected during the following periods: 7 February 1996 (two males; 28.2 and 31.0 mm SVL), October–November 1996 (five males; mean = 31.2 ± 0.06 mm SVL), and January 1997 (two males; 29.9 and 32.0 mm SVL). All specimens were collected 15 km northeast of Corrientes (27°28'S, 58°50'W), Corrientes, Argentina. *Phyllomedusa hypocondrialis* is a sit-and-wait predator. Table 1 summarizes data collected during this study.

I thank Arturo I. Kehr for suggestions on field and laboratory methods and for reviewing a draft of this manuscript.

PHYSALAEMUS PUSTULOSUS (Túngara Frog). **PREDATION.** Although primarily nocturnal, *Physalaemus pustulosus* are active during the day on Toboga Island, Republic of Panama. *Physalaemus pustulosus* were heard calling, observed mating, and seen moving about the forest throughout the day (0700–1800 h, May–June 1998). On 15 June 1998 at 1030 h, we observed an adult *P. pustulosus* being attacked and dragged into a crevice under a boulder by an adult female tarantula, *Sericopelma rubronitens*. Toboga Island has a large population of tarantulas, with adult females (>100 mm in body length) encountered frequently (diurnal censusing yielded approximately 1 spider per 2 m^2).

To examine if *P. pustulosus* were being consumed by *S. rubronitens*, a thread was tied around a live frog's waist and the frog was placed on the leaf litter near a foraging tarantula. The spider pounced on the frog as soon it tried to hop away. The tarantula briefly handled the frog before inserting its fangs, and then carried the frog under a rock overhang. After 3 h, the tarantula was seen moving away from the overhang. The *P. pustulosus* was retrieved for examination and found to be flaccid with most of its tissues digested and removed. The frog's skin was intact except for the area under the left forelimb where the tarantula's fangs had been inserted. The carcass was surrounded by a thin veil of spider silk.

Unlike the majority of *P. pustulosus* predators, which locate the frogs through orientation to calls (Ryan 1985. The Túngara Frog. The University of Chicago Press, Chicago, Illinois. 230 pp.), these tarantulas use vibrational cues to locate prey. The spiders therefore present a threat to *P. pustulosus* during movement to and from breeding ponds. As both these spiders and frogs are more active at night, the incidence of tarantula predation on *P. pustulosus* is probably frequent on Toboga.

Submitted by **HEATHER M. GRAY**, and **DAVID M. GREEN** Redpath Museum, McGill University, 859 Sherbrooke Street West, Montreal, Quebec H3A 2K6, Canada, and **M. JASON PETERS**, Department of Biology, La Sierra University, Riverside, California 92515, USA.

RANA CASCADAE (Cascade Frog). **PREDATION**. On 11 September 1996, we released a male *Rana cascadae* (35 mm SVL) in Long Lake, Klamath County, Oregon, USA (T35S R5E Sec 27). It was immediately seized by a large (38 mm TL) giant water bug (*Lethocerus* sp.) which was concealed in the silty lake bottom. The frog was retrieved within 30 s from the water bug and was suffering paralysis throughout its body. The frog was breathing but all limbs were limp and no response to touch was observed. After ca. 10 min. the frog began to regain use of its limbs and was released. Giant water bugs are known predators of anuran larvae (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill Book Co., New York. 670 pp.) and in laboratory experiments giant water bugs readily fed on *R. cascadae* tadpoles (Peterson and Blaustein 1992. Copeia 1992:577–584). We know of no previously published records of giant water bugs preying on adult frogs.

Submitted by **RICHARD S. NAUMAN**[1] and **YVONNE DETTLAFF**[2], Chiloquin Ranger District, Winema National Forest, 38500 Hwy 97 North, Chiloquin, Oregon 97624, USA. [1]Present Address: PNW Research Station, USDA Forest Service, 3200 SW Jefferson Way, Corvallis, Oregon 97331, USA. [2]Present Address: USDA Forest Service, 2020 Toketee Ranger Station, Idelyld Park, Oregon 97447, USA.

RANA LUTEIVENTRIS (Columbia Spotted Frog). **CANNIBALISM**. Intraspecific predation is well documented in ranid frogs (Crump 1992. *In* Elgar and Crespi [eds.], Cannibalism: Ecology and Evolution Among Diverse Taxa, pp. 256–276. Oxford Univ. Press, New York), but is infrequently reported among ranid species in western North America. Despite several dietary studies of *R. luteiventris* (Turner 1959. Am. Midl. Nat. 61:403–413; Miller 1978. Northwest Sci. 52:243–249; Whitaker et al. 1983. Northwest Sci. 57:147–154), cannibalism has not been documented. However, intraspecific predation has been observed in Oregon spotted frogs (*R. pretiosa*) (M. P. Hayes, pers. comm.) and may be more prevalent than generally recognized. Herein, I report intraspecific predation of a metamorphosing juvenile by an adult *R. luteiventris*.

During a 5 September 1997 amphibian survey in a high-elevation (2484 m) lake, I observed an adult female *R. luteiventris* (ca. 75 mm SVL) consuming a metamorphosing conspecific (ca. 25 mm SVL; Gosner stage 42–43). The adult female was captured, with the metamorphosing frog in her mouth, along the marshy shoreline of a small (0.2 ha), unnamed lake (UTM Zone 11, E688900, N4998200) in the Bighorn Crags of the Frank Church-River of No Return Wilderness, Lemhi County, Idaho, USA.

Adult anurans do not appear to distinguish conspecifics from other prey (Duellman and Trueb 1986. Biology of Amphibians, John Hopkins University Press, Baltimore, p. 246). Therefore, cannibalism on juveniles by adults may simply represent utilization of an available food source. In the short, ice-free season of oligotrophic, high-elevation lakes, the consumption of abundant metamorphosing juvenile frogs by conspecific adults may be an important nutrient-rich food source for *R. luteiventris*. Intraspecific predation has been shown to increase nutrition and growth compared to other food sources (Crump 1990. Copeia 1990:560–564; Lannoo 1989. Can. J. Zool. 67:1911–1914; Wildy et al. 1998. J. Herpetol. 32:286–289). This may be particularly important in high-elevation lakes that typically have low productivity.

I thank Marc P. Hayes, John Lee, Charles R. Peterson, Dave Ross, and Elena Velasquez for commenting on an earlier version of this note, and Peter Ritson for his assistance with this observation.

Submitted by **DAVID S. PILLIOD**, Herpetology Laboratory, Department of Biological Sciences, Idaho State University, Pocatello, Idaho 83209-8007, USA.

RANA SPHENOCEPHALA (Southern Leopard Frog). **REPRODUCTION (FALL BREEDING).** In the southern portion of its range, *Rana sphenocephala* is known to breed during every month of the year (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agri. Exp. Station. Auburn, Alabama. 347 pp.; Dundee and Rossman 1991. The Amphibians and Reptiles of Louisiana. Louisiana State University Press. Baton Rouge, Louisiana. 300 pp.). Caldwell (1986. Copeia 1986:249–253), however, reported that even in these areas, breeding occurred in two primary time periods; early fall and winter. Smith (1961. The Amphibians and Reptiles of Illinois. Illinois Nat. Hist. Sur. Bull., 28[1]. Illinois Natural History Survey Division, Urbana, Illinois. 298 pp.) reported that the breeding season for *R. sphenocephala* in Illinois is March and April and that transforming frogs can be found in June and July. Wright and Wright (1949. Handbook of Frogs and Toads, 3rd ed. Comstock Publ., Ithaca, New York. 640 pp.) observed ten *R. sphenocephala* egg complements south of Olney, Richland County, Illinois on 11 September 1929.

This note supports the Wrights' observation of fall breeding in *R. sphenocephala* in Illinois. Newly hatched tadpoles and egg masses were observed on 30 September 1996 in a recently filled, rainwater pond located 5.5 km E Ullin, 0.5 km S Cache River, E side Cache Chapel Road, Pulaski County, Illinois, USA (T14S R1E NW 1/4 Sec. 21; UTM Zone 16: N4127970m, E312475m).

Tadpoles were brought back to the laboratory and raised through metamorphosis to verify identification. In March 1997, 18 tadpoles successfully metamorphosed and positive identifications were made. Six metamorphs were vouchered in April (Illinois Natural History Survey 12981–12986); the remainder were released on 4 July 1997 at the site of capture. At the time of release, hundreds of *R. sphenocephala* tadpoles and metamorphs were observed. Because the hydrology of the pond is unknown from October 1996 to July 1997, we do not know if these tadpoles and metamorphs represent progeny of Fall 1996, Spring 1997, or both.

The range of the southern leopard frog in Illinois extends into the northern third of the state. The Wrights' Richland County and our Pulaski County observations fall within the southern third of the state. It is not known if fall breeding occurs near the northernmost edge of the range of *R. sphenocephala* in Illinois.

Submitted by **JOHN E. PETZING** and **CHRISTOPHER A. PHILLIPS**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

RANA SYLVATICA (Wood Frog). **COLORATION**. An albino *Rana sylvatica* tadpole was collected in St. Croix County, Wisconsin, USA, during Spring 1996. Several albino tadpoles were also observed in the area. The tadpole was raised in captivity and has reached 50 mm SVL as an adult. The specimen is being kept alive at the J. F. Bell Museum of Natural History and will be added to the vertebrate collection upon its death. The frog is ivory yellow with a pinkish mask. This is the first report of albinism in *R. sylvatica*.

Submitted by **DON LUCE**, J. F. Bell Museum of Natural History, 10 Church Street SE, Minneapolis, Minnesota 55455, USA, and **JOHN J. MORIARTY**, Hennepin Parks, 3800 County Road 24, Maple Plain, Minnesota 55359, USA.

RANA SYLVATICA (Wood Frog). **PREDATION**. On 26 May 1998 while electrofishing along the north shoreline of Pigeon Lake at the Pigeon Lake Field Station, Bayfield County, Wisconsin, USA (T45N R8W Sec 26), I collected a juvenile largemouth bass (*Micropterus salmoides*), 112 mm TL, that had captured a *Rana sylvatica* (29 mm SUL). The frog had been swallowed hind feet first up to the insertion of the forelimbs, and was still alive (largemouth bass often capture prey that are too large to swallow in one gulp and swim with them partially swallowed as digestion proceeds). Although largemouth bass are well known to prey on frogs (e.g., Cochran 1982. Herpetol. Rev. 13:45–46), fish were not included among the predators of wood frogs listed in recent field guides to the herpetofauna of the upper Midwest (Vogt 1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum. 205 pp.; Oldfield and Moriarty 1994. Amphibians and Reptiles Native to Minnesota. Univ. Minnesota Press. 237 pp.; Harding 1997. Amphibians and Reptiles of the Great Lakes Region. Univ. Michigan Press. 378 pp.). Presumably this reflects the wood frog's tendency to inhabit terrestrial environments and to breed in temporary fishless ponds. Relatively high water levels in Pigeon Lake in 1998 may have brought wood frogs and largemouth bass into closer proximity that usual by flooding areas of woody shoreline vegetation.

Submitted by **PHILIP A. COCHRAN**, Division of Natural Sciences, St. Norbert College, DePere, Wisconsin 54115, USA.

SCAPHIOPUS HOLBROOKI HURTERII (Hurter's Spadefoot). **PREDATION**. Recently metamorphosed Hurter's spadefoots were found in 25 samples during a crop analysis of 1767 northern bobwhites (*Colinus virginianus*) harvested between December 1995 and February 1996 from near Encino, Brooks County, Texas, USA. Three specimens (mean SVL = 16.6 mm) were deposited in the Texas Cooperative Wildlife Collection, Texas A&M University, College Station (TCWC 80162–164).

Although *Scaphiopus* spp. have been described as producing odors that are disagreeable to humans (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians. Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.), there are no experimental data on the effects of these odors or secretions on potential predators (Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill Book Co., New York. 670 pp.).

Scaphiopus spp. migrate en masse at metamorphosis (Neill 1957. Herpetologica 13:185–187). Neill (*op. cit.*) observed mockingbirds and jays in the vicinity of a *Scaphiopus* mass migration but did not observe any predation by these birds. We suspect that predation by northern bobwhite on spadefoots is rare and limited to those times when coveys of quail fortuitously encounter mass migrations of metamorphosing spadefoots. However, because northern bobwhite coveys can contain as many as 16 adults (Lehmann 1984. Bobwhites in the Rio Grande Plain of Texas. Texas A&M Univ. Press, College Station. 371 pp.) and consume as many as 10 toadlets per individual (this study), these rare predation events may be locally important in spadefoot population dynamics.

TESTUDINES

CHRYSEMYS PICTA BELLII (Western Painted Turtle). **EARLY EMERGENCE**. On 7 April 1997, a hatchling *Chrysemys picta bellii* (James Ford Bell Museum of Natural History 13513) was found dead on a road in Shoreview, Ramsey County, Minnesota, USA. This was within a week of snowmelt. The winter of 1996–97 was one of early and heavy snow. This snow kept the ground from freezing. Once the snow melted the soil warmed up quickly, but was still not above 10°C when the hatchling was found. The temperature for the week of 1–7 April 1997 averaged 10°C with a high of 21°C, which was 5°C above normal. The month as a whole was 2°C below normal. Overwintering *C. picta bellii* hatchlings normally emerge in late May to early June. This is the earliest known emergence for this species at this latitude (Oldfield and Moriarty 1994. Amphibians and Reptiles Native to Minnesota. University of Minnesota Press, Minneapolis, Minnesota. 237 pp.).

Submitted by **JOHN J. MORIARTY**, Hennepin Parks, 3800 County Road 24, Maple Plain, Minnesota 55359, USA.

CHRYSEMYS PICTA BELLII (Western Painted Turtle). **HATCHLING EMERGENCE.** *Chrysemys picta bellii* in British

Columbia is at the extreme northwestern edge of its range. Females are known to lay multiple clutches of eggs at more southerly locations, but produce at most one clutch per year in British Columbia (Gregory and Campbell 1984. The Reptiles of British Columbia. British Columbia Provincial Museum, Victoria, British Columbia. 102 pp.). In northern populations, eggs hatch in late summer, hatchlings overwinter in the nest and emerge the following spring (St. Clair and Gregory 1990. Copeia 1990:1083–1089). Hatchlings have well-developed freeze tolerance, and can endure periods of freezing temperatures in the nest (Rubinsky et al. 1994. Am. J. Physiol. 267:R1078–R1088). There have been no previously published reports of viable hatchlings emerging from the nest in the fall in British Columbia, although St. Clair and Gregory (*op. cit.*) found a dead hatchling on the ground by a nest in September 1988.

On 18 September 1998, in the Creston Valley Wildlife Management Area, British Columbia, Canada (49°12'N, 116°38'W) we found the opening of a turtle nest. It was a small hole (ca. 5 cm across) in a dirt road leading down to the Kootenay River on a southwest-facing slope, about 20 m from the water. The opening to the nest did not appear to have been dug out by a predator. There were pieces of shell and two partly opened eggs with dried yolk in them on top of the rocks inside the hole; when these were removed, we could see a small turtle inside the hole, partly buried in the dirt and pebbles. It had been raining off and on all day, the first significant rain in over a week, and the air temperature was 20°C. As the rain began again, the turtle started to move around in the hole, and eventually dug itself out and climbed out of the hole. It had an egg tooth, and its carapace was about 3 cm long. The turtle immediately moved to the nearest vegetation at the side of the road. Meanwhile, a second hatchling appeared at the opening, moved uphill a short distance, then turned and went into the vegetation. Turtle breeding in Creston was about two weeks early in 1998 (pers. obs.); the fall hatchling found by St. Clair and Gregory (*op. cit.*) was from the first nest observed the previous mating season. Therefore, it is possible that an atypically long growing season may allow hatchlings to leave the nest before winter.

PSEUDEMYS FLORIDANA PENINSULARIS (Peninsula Cooter) and ***P. NELSONI*** (Florida Redbelly Turtle). **MUTUALISM**. For turtles that ambush their prey, an algae-covered carapace may provide camouflage from predators and prey (Neill and Allen 1954. Ecology 35:581–584). However, algal growth on the carapace could be pathological if, for example, the algae spread to the skin (Neill and Allen, *op. cit.*). Turtles can remove algae from their carapace by basking and shedding (Neill and Allen, *op. cit.*), biting algae off of their own shells (Reilly 1983. Herpetol. Rev. 14:76), and by biting algae off of conspecifics (Meshaka 1988. Herpetol. Rev. 19:88). Here, we report individuals of two different species of turtles removing algae from each other, an interaction that approaches interspecific mutual grooming.

On 11 May 1996 at 1445 h we watched a male *Pseudemys nelsoni* eating algae from the carapace of a female *P. floridana peninsularis* in Taylor Slough at Anhinga Trail, Everglades National Park, Dade County, Florida, USA. For six minutes, we observed the male removing algae from the rear of the female's carapace. During this time, the female's head was above water and she moved only passively from the actions of the male. Our observations ended when the actions of the male moved both turtles behind vegetation. We do not know how long this interaction had been taking place; however, there was a mosaic of freshly cleared patches on the pleurals of the female's carapace, suggesting that the male had been foraging for some time prior to our arrival.

On 27 May 1996 from 1010 to 1100 h, also at Anhinga Trail, WEM watched a female *P. f. peninsularis* feeding on the algae from the carapace of a female *P. nelsoni*. With each bite, the *P. f. peninsularis* would use her forefeet to push herself from the other turtle, removing algae in the process. The *P. nelsoni* made no attempt to avoid the *P. f. peninsularis*. At 1100 h, a second female *P. nelsoni* arrived along with a male *P. nelsoni*. The shells of both of these turtles were covered with algae. The *P. f. peninsularis* and male *P. nelsoni* foraged on the carapace of the second *P. nelsoni* female until 1105 h, after which the second female *P. nelsoni* swam away. At 1115 h, the original *P. nelsoni* female swam 0.5 m from shore, where she had been feeding on aquatic plants, to the female *P. f. peninsularis* and each fed from the other's carapace. From 1117 to 1123 h the male *P. nelsoni*, having found and swam around both turtles, positioned himself on top of the female *P. nelsoni*, vibrating his forefeet over her head in courtship. Throughout courtship attempts, the *P. f. peninsularis* alternately foraged on the rear of both turtles, often pulling the male from the female *P. nelsoni*. The male repeatedly moved above the female after these disruptions. At 1123 h, the *P. f. peninsularis* swam away from the courting pair of *P. nelsoni*.

As suggested for intraspecific algal grazing (Meshaka, *op. cit.*), this interspecific grazing behavior is suggestive of mutualism, whereby one individual receives nutrition and the other is relieved of a potential burden. Although basking sites were plentiful at this site, the carapaces of turtles of both species were covered with algae, perhaps because of the high pH, temperature, and eutrophication of the slough. Because of these conditions, the rate of algal growth on turtle carapaces might exceed that which can be removed during normal basking or shedding. Thus, it is possible that mutual algal grazing in these two species is adaptive. We thank James L. Dobie for commenting on this manuscript.

TERRAPENE CAROLINA CAROLINA (Eastern Box Turtle). **DIET**. *Terrapene carolina* is regarded as omnivorous, eating a wide variety of plant and animal foods. Reptiles documented as food items, typically as carrion, include lizards (*Phrynosoma*), turtle eggs (*Chelydra*), and snakes (*Carphophis*, *Coluber*, *Storeria*, *Thamnophis*) (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institutional Press, Washington, D.C. 578 pp). On 20 August 1998, in Monroe County, Georgia, USA, I observed an adult male *T. carolina carolina* eating the entrails of a road-killed juvenile *Agkistrodon contortrix*. As I approached, rather than retracting its head into its shell, the turtle bit down firmly on the snake and carried it off the road and away from me. I know of no other reported observations of box turtles consuming road-killed venomous snakes.

TERRAPENE ORNATA LUTEOLA (Desert Box Turtle). **HOMING BEHAVIOR.** Many turtle species seem to exhibit homing behavior and can return to their home range after being displaced up to several km away (Cagle 1944. Misc. Publ., Mus. Zool., Univ. Michigan 61:1–37; Gibbons and Smith 1968. Herpetologica 24:331–333). Box turtles (*Terrapene* spp.) have shown some tendency to exhibit homing behavior when experimentally moved. Eastern box turtles (*T. carolina*) have been able to return to their home range when displaced up to 1.2 km (Nichols 1939. Copeia 1939:125–127; Posey 1979. Bull. Maryland Herpetol. Soc. 15:139–140), but did not return when displaced greater than 1.6 km (Nichols 1939, *op. cit.*; Posey 1979, *op. cit.*; Schwartz and Schwartz 1974. Missouri Dept. Conserv. Terr. Ser. 5:1–28). Ornate box turtles (*T. o. ornata*) have shown the ability to return to their home range from up to 2.8 km away (Metcalf and Metcalf 1970. Trans. Kansas Acad. Sci. 73:96–117; Metcalf and Metcalf 1978. J. Herpetol. 12:411–412). We found a desert box turtle (*T. ornata luteola*) that appears to have returned over 9 km to its home range after accidentally being displaced.

We have been studying a population of *Terrapene ornata luteola* at the Sevilleta National Wildlife Refuge, 85 km south of Albuquerque, New Mexico, USA, since 1986. Turtles have been found while driving dirt roads (Nieuwolt 1996. Herpetologica 52:487–495). When encountered, turtles were marked by filing scutes (Cagle 1939. Copeia 1939:170–173) and most were put into a container for transport back to facilities where additional data were recorded. Turtles were returned to the site of capture and released within 1–7 d. Besides turtles that we found, we occasionally received unmarked turtles from others working in the area. Location data always accompanied these turtles. However, field notes and data sheets indicate that one turtle probably was not returned to its point of capture. On 20 September 1986, we received an adult female (116 mm CL, 373 g). After processing, we returned her the next day to what we understood to be her capture location near the northern end of our study site. We did not capture her again until 14 July 1988, when we found her 9.15 km south of the site where she had been released. This turtle was recaptured 18 times during 1990–1992. Each capture was within a well-defined area 8.10–8.75 km from her original release site. Because this adult female made one long-distance move and then settled into a fixed area, we feel certain that she returned to her original home range after accidentally being displaced in 1986.

LACERTILIA

ABRONIA MIXTECA (NCN). **REPRODUCTION.** The anguid lizard *Abronia mixteca* is known only from seven pine-oak forested localities in the Sierra Madre Occidental of the Mexican states of Guerrero and Oaxaca (Bogert and Porter 1967. Amer. Mus. Novitates 2279:1–21; Campbell and Frost 1993. Bull. Amer. Mus. Nat. Hist. 216:1–121). Little is known about its reproduction. Herein we report observations of reproduction in captive individuals.

On 29 July 1995 at 1100 h an adult male (WSB 716-1, 115 mm SVL, 130 mm TL) was collected near the type locality at El Tejocote, Oaxaca (17°56'14"N, 97°33'03"W), elev. 2286–2400 m. The next day an adult female (WSB 716-2, 100 mm SVL, 125 mm TL) was collected in a disturbed oak forest at km 156.5 on the Tehuacán-Oaxaca Federal Hwy. 135 (17°36'83"N, 97°19'58"W), elev. 2287 m.

In the laboratory the specimens were housed together in a glass terrarium (70 x 50 x 50 cm). On 1 August 1998 at 0800 h the pair was found mating, the male grasping the female on the temporal region, and their tails loosely intertwined, as described by Campbell and Frost (*op. cit.*) for *Abronia lythrochila*. The lizards did not disengage until about 1600 h. Afterwards, the pair continued to be housed together. On 26 February 1996, seven months (210 days) after copulation, the female gave birth to seven live young (mean SVL 35.57 mm, SD 0.53, range 35–36 mm; mean TL 42 mm, SD 1.29, range 40–44 mm; mean mass 0.81 g, SD 0.069, range 0.7–0.9 g). The neonates were pale golden yellow with 5–6 black bands on the body, which were not continuous, but formed by a series of irregular black spots. There were 12–14 black rings on the tail, and the head had some black markings. The color pattern of the young differed from that of adults, which were bright light green dorsally with some irregular, black blotches on the body and tail.

The litter size is within the range for that of other anguids (range 1–12 young). Our observations suggest that *A. mixteca* mates during the summer and the offspring are born in the spring.

We thank Mario Mancilla and W. C. Sherbrooke for assistance in the field. W. C. Sherbrooke also provided financial support for the field work. We thank Ubaldo Guzmán for assistance in the lab.

ANOLIS CASILDAE (NCN). **FORAGING.** *Anolis casildae* is a large anoline species recently described from Panama (Arosemena et al. 1991. Rev. Biol. Trop. 39:255–262), and for which nothing is known of its natural history. On 23 November 1997, while collecting this species in western Panama, Provincia de Chiriquí, I observed a large (108 mm SVL, 23.0 g mass, CRE 7665, University of Miami) male *A. casildae* leap from the ground to a sapling (2 cm diam) and perch ca. 0.5 m above the ground. While perching head-up on this sapling, the lizard began to consume a large green katydid (Orthoptera). Subsequently, the lizard was captured and found to be missing its left forearm. The distal portion of the remaining arm fragment was scarred but well healed, with a tiny bone fragment protruding from the tip. The injury may have been the result of a predation attempt. The missing forelimb appeared to have little effect on locomotion, as the anole captured the katydid with little difficulty, moved easily to the sapling to feed, and even managed to escape and evade capture for several minutes in the dorm room of the field station.

I thank the Smithsonian Tropical Research Institute for help with all aspects of collecting in Panama. I also thank Stan Rand, Roberto Ibañez, and the Herpetological Circle for encouragment and help while in Panama. This work was supported by a Tropical Biology Fellowship from the Department of Biology, University of Miami.

CNEMIDOPHORUS SEXLINEATUS (Six-lined Racerunner). **ACTIVITY.** As is typical for *Cnemidophorus* species, *C. sexlineatus* is a highly active heliotherm that narrowly maintains a relatively high body temperature during a restricted activity period (Bogert 1949. Evolution 3:195–211; Fitch 1958. Univ. Kansas Publ. Mus.

Nat. Hist. 11:11–62; Hardy 1962. Univ. Kansas Sci. Bull. 43:1–73; Paulissen 1988. J. Herpetol. 22:473–476). Although *C. sexlineatus* has a wide geographic distribution in North America extending from New Jersey to Florida west to southern North Dakota and eastern New Mexico (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians. Houghton Mifflin Co., Boston, Massachusetts, 450 pp.), activity periods and field body temperatures have been reported for relatively few populations (Florida, Bogert, *op. cit.*; Kansas, Fitch, *op. cit.*, Hardy, *op. cit.*; Oklahoma, Carpenter 1960. Proc. Oklahoma Acad. Sci. 41:72–77.; Paulissen, *op. cit.*). Here we document diel activity and body temperatures of *C. sexlineatus* from a population occupying a 400 m stretch of active railway trackbed in Searcy, White Co., Arkansas, USA.

On each of seven days between 28 July and 8 September 1985, one of us (RER) censused the active lizards on the study area every two hours from 0600 to 2000 h by slowly walking its length one time and recording all active *C. sexlineatus* observed by sex and age class (juvenile vs. adult). In addition, lizards were captured using a fishing pole with an attached 0.5 m length of monofilament line and a small hook baited with a cricket. We immediately measured each captured lizard's cloacal temperature with a Schulteis thermometer, and then sexed, measured (SVL), and released it at the site of capture. Air and soil surface temperatures were recorded at the onset of each census.

A total of only three lizards was observed on two overcast, rainy days when maximum soil surface temperatures reached only 26.4° and 29.2°C, respectively. On five cloudy or clear days, when maximum soil temperatures reached 41.2–52.0°C, a total of 203 lizard observations was made. Over these five days, no lizards were observed at either 0600 or 2000 h and only two lizards were observed at 0800 h and 10 lizards at 1800 h. Most lizards (94.1%) were active between 1000 and 1600 h when an average of 47.8 (SD = 13.0) lizards were observed at each census time (data pooled over five days). Mean activity temperature (Pough and Gans 1982. *In* C. Gans, ed., Biology of the Reptilia, Physiology C, Vol. 12, pp. 17–23. Academic Press, New York), calculated from body temperatures of 53 active lizards, was 40.7°C (SD = 0.20, range 36.9–42.8). Mean activity temperatures did not differ among juveniles (mean = 40.6°C, SE = 1.03), males (mean = 40.7°C, SE = 0.30) or females (mean = 40.7°C, SE = 0.28) (ANOVA, $F_{2, 50} = 0.006$, $P>0.99$).

Diel activity of *C. sexlineatus* at this locality was unimodal and restricted to the warmer parts of clear or partly cloudy days. Body temperature during activity was characterized by a relatively high mean and low variance (CV = 0.49%). These results are similar to those documented for the thermophilic *C. sexlineatus* in other parts of its range and reflect adaptations resulting in restricted activity times for *Cnemidophorus* spp. in general (Lowe 1991. *In* J. W. Wright and L. J. Vitt [eds.], Biology of Whiptail Lizards [Genus *Cnemidophorus*], pp. 1–25. Oklahoma Mus. Nat. Hist. Norman).

EUMECES LATICEPS (Broad-headed Skink). **FORAGING BEHAVIOR.** On 22 May 1995 at 1200 h, two adult *Eumeces laticeps* were observed in a tree at the Village Creek Historical Park in Arlington, Texas, USA. Both were chasing hackberry butterflies (*Asterocampa celtis*), which were feeding on resins from an American elm (*Ulmus americanus*). The skinks were about 2.5 m above the ground. They made numerous attempts to capture the butterflies as they landed on the tree. After several failed attempts, one of the lizards waited until a butterfly flew past. The skink then leaped from its perch and narrowly missed a mid-flight capture of the butterfly. The lizard returned to its original perch site and made a second attempt to capture its prey in the same manner. *Eumeces laticeps* has been described as the most arboreal skink in North America (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.).

LEIOSAURUS BELLI (NCN). **CLUTCH.** Data on the natural history of *Leiosaurus belli* (Polychridae) are scarce (Cei 1986. Reptiles del Centro, Centro Oeste y Sur de la Argentina, Mon. IV, 527 pp.). On 15 January 1993 two female *L. belli* were collected by FD'H in maritime sand dunes near Las Grutas beach, 18 km SW San Antonio Oeste (40°44'S, 64°57'W, San Antonio Department, Río Negro Province, southeastern Argentina. The lizards were maintained in a glass terrarium with sand substrate. On 18 January 1993, one female (102 mm SVL, 210 mm TL, not weighed) oviposited 15 white eggs (mean = 15.3 mm x 8.8 mm) in 30 minutes. Four days later, the other female (96 mm SVL, 195 mm TL, not weighed) oviposited 11 white eggs (mean = 14.2 mm x 8.8 mm) in 30 minutes. Both clutches were placed in a small container with sand and moist humus until their arrival in the laboratory. Upon arrival the eggs were discarded, as they appeared to be in bad condition. This is the first report on clutch size in *L. belli*. Nothing is known of the reproductive behavior of this species in the wild.

Submitted by **LUCIANO JAVIER AVILA**, CRILAR-CONICET, Mendoza y Entre Ríos s/n, 5301, Anillaco, La Rioja, Argentina, and **FEDERICO D'HERVÉ,** Instituto Superior de Formación Docente de Villa Regina, Alem 250, 3816, Villa Regina, Río Negro, Argentina.

LEPIDOPHYMA LOWEI (Lowe's Tropical Night Lizard). **REPRODUCTION**. No previously published reproductive data are available for *Lepidophyma lowei* (Bezy and Camarillo 1997. Contrib. Sci. 465:1–8). A female *L. lowei* collected at the type locality on 7 April 1991 was maintained in captivity and gave birth to four offspring on 27–29 April 1991: 27 April at 1500 h; 28 April at 1200–1400 h and at 2030–2120 h; and 29 April (time unknown). The extraembryonic membranes were not present and may have been eaten by the mother. No dead newborns or undeveloped eggs were observed. The female had a SVL of 60 mm, and weighed 5.50 g before and 3.32 g after parturition. The newborns weighed 0.29 g, 0.32 g, 0.33 g, and 0.31 g in order of birth.

These observations document viviparity in an additional species of xantusiid lizard and indicate that *Lepidophyma lowei* has a smaller litter size than most other members of the genus (Aguilar Cortes et al. 1990. Southwest. Nat. 35:373–374). The specimens were deposited in the Colección Herpetológica, Escuela Nacional de Estudios Profesionales Iztacala (ENEPI 3804-07).

PHYMATURUS PATAGONICUS (Argentine Chuckwalla). **FACULTATIVE PARTHENOGENESIS.** In April 1991, BG purchased an adult *P. patagonicus,* which, although not measured at the time of purchase, measured 17 cm total length on 20 June 1998. It was kept alone in captivity from the time it was purchased. On or about 5 May 1998, the lizard produced a single, female offspring, which is still alive, and measured 9.5 cm total length on 20 June 1998 (Fig. 1). On 27 May 1998 a stillborn female (ca. 7 cm total length, 57 mm SVL) was assist-delivered, apparently fully-developed. It expired, however, presumably from the inability of the mother to extrude it. Sex of both neonates was determined by the absence of well-defined preanal pores.

The dead neonate was referred to the *Phymaturus patagonicus* complex of viviparous, herbivorous lizards from Argentina, by Richard Etheridge, who also recalled that Lamborot and Navarro-Suárez (1984. Herpetologica 40:258–264) karyotyped the congeneric *P. palluma*. That study revealed that males are the heterogametic sex, with 32+3 chromosomes (autosomes + genosomes), including a Y chromosome; females have 32+4 chromosomes, and lack a Y chromosome. Assuming that *P. patagonicus* is similar to *P. palluma*, we suggest that, in the absence of cytological proof, the two offspring, both being female, could have been produced by facultative parthenogenesis. The only alternative explanation is sperm retention (amphigonia retardata), which is unlikely for a period of seven years; the longest record of sperm retention in reptiles was reported by Haines (1940. Copeia 116–118), who observed fertile eggs (none of which hatched) laid by a *Leptodeira septentrionalis polysticta* after five years of isolation.

Facultative parthenogenesis has been shown to occur in snakes by Schuett et al. (1998. Herpetol. Nat. Hist. 5:1–10), who also note evidence of occurrence in lizards of the genera *Basiliscus* and *Iguana*. Herein we add another genus and family (Tropiduridae) to the list of probabilities.

Thanks to Richard Etheridge for identification and assistance with the literature.

FIG. 1. Mother and daughter *Phymaturus patagonicus*.

SMITH**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA.

SCELOPORUS UNDULATUS ELONGATUS (Northern Plateau Lizard). **EGG LAYING**. Very little is known about the life history and ecology of *Sceloporus undulatus elongatus* in Wyoming, the northern distribution limit for the subspecies (Baxter and Stone 1980. Amphibians and Reptiles of Wyoming. Wyoming Game and Fish Department). Previously I have reported mating behavior (Ashton 1998. Herpetol. Rev. 29:102) of this subspecies in Wyoming. Here I describe egg laying behavior, observed ca. 70 km (by air) SW of Rock Springs, Flaming Gorge National Recreation Area, Sweetwater Co., Wyoming, USA.

On 12 June 1998, from 1145 h to 1200 h, I observed an adult female *S. u. elongatus* (76.0 mm SVL, 96.0 mm tail length, 10.0 g mass post-partum). At 1145 h her anterior body was exposed while her posterior was under a small rock. She was not making any movements at this time. Then at 1150 h she moved most of her body out from under the rock and began digging with her hind limbs, pushing dirt over the eggs that she had just laid. She finished covering the eggs with dirt at 1200 h, at which time I captured her. She had distinct lateral folds, verifying that she had just laid eggs. I palpated her and did not detect any more eggs within her body cavity.

Submitted by **KYLE G. ASHTON**, Department of EPO Biology, Campus Box 334, University of Colorado, Boulder, Colorado 80309, USA.

UROSAURUS MICROSCUTATUS (Small-scaled Lizard). **ENDOPARASITES**. *Urosaurus microscutatus* occurs from Imperial and San Diego Counties, California south to the vicinity of El Medaño, Baja California (Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. 2nd ed., Houghton Mifflin Co., Boston, Massachusetts. 336 pp.). There are no reports of endoparasites from this species. This note reports helminths from *U. microscutatus* from southern California.

Ten male *U. microscutatus* (mean SVL = 45.0 mm ± 2.5 SD, range 41–48) collected in 1953, 1956–57, 1966, 1972–1973, and 1997, were borrowed from the Natural History Museum of Los Angeles County (LACM 97828–97830, 97832, 97834, 122066, 123398–12399) and San Diego State University (SDSU 3772–3773). Nine were from San Diego County; one was from Imperial County. The lizards had been fixed in 10% formalin and preserved in 70% ethanol (LACM) or 55% isopropanol (SDSU). The body cavity was opened by a longitudinal incision. The esophagus, stomach, small and large intestine were removed and examined with a dissecting microscope. The body cavity and liver were also examined. One ten-segment strobila of a cestode was found in the small intestine. It was stained with hematoxylin, mounted in balsam and identified as *Oochoristica* sp. The immaturity of the specimen prevented assignment to a species. Two species of nematodes were found in the large intestine and identified using a glycerol wet mount: *Spauligodon giganticus* and *Strongyluris rubra*. *Urosaurus microscutatus* is a new host record for these helminths.

Prevalence (number infected individuals divided by number of indiviuals examined) was 10% for *Oochoristica* sp.; 20% for *Spauligodon giganticus* (11 and 5 nematodes in 2 lizards); 10% for *Strongyluris rubra* (9 nematodes in 1izard). Helminths were deposited in the U.S. National Parasite Collection, Beltsville, Maryland: *Oochoristica* sp. USNPC 87999; *Spauligodon giganticus* USNPC 88000; *Strongyluris rubra* USNPC 88001. The related species *Urosaurus graciosus* from Los Angeles County, California (Goldberg et al. 1993. Bull. South. California Acad. Sci. 92:43–51) was found to harbor *Oochoristica* sp. and a single third stage larva, *Physaloptera* sp. *Urosaurus ornatus* from New Mexico harbored the cestodes, *Mesocestoides* sp. and *Oochoristica* sp., the nematodes *Spauligodon giganticus* and *Physaloptera* sp. (third stage larvae); *U. ornatus* from Arizona harbored *S. giganticus* (Goldberg et al. 1993. J. Helm. Soc. Washington 60:118–121.

We thank Robert L. Bezy (Natural History Museum of Los Angeles County) and Tod Reeder (San Diego State University) for permission to examine *U. microscutatus*.

SERPENTES

BITIS NASICORNIS (Rhinoceros Viper). **DERMATOPHAGY.** Dermatophagy by captive snakes is well documented (Weldon et al. 1993. J. Herpetol. 27:219–228, and references therein). Although I was unable to locate any literature regarding this behavior in rhinoceros vipers (*Bitis nasicornis*), I did find one account of shed skin consumption in another viperid, *Bitis arietans* (Haagner 1991. The Naturalist 35:32–33). It has been suggested that this behavior may be coincidental or related to reptile-eating in snakes (Groves and Groves 1972, Herpetologica 28:45–46). Other authors have speculated that dermatophagy in snakes may be used to eliminate evidence of the animal's location (Weldon et. al. 1993, *op. cit.*).

On 6 April 1998, I observed a three year old captive-born *Bitis nasicornis* (SVL = 737 mm; TL = 876 mm) in ecdysis at 0945 h. Approximately four minutes lapsed until the snake completed half of the shedding process. At this point, the animal removed the dead skin from its body and began consuming it. The snake then completed ecdysis, but it did not consume the remaining skin.

This specimen was housed in a plastic enclosure (90.8 x 44.5 x 44.5 cm) with a hide box, water bowl, and slabs of cork bark. It was misted twice weekly and fed a diet of adult mice (*Mus musculus*) once a week. No subsequent observations of this behavior have been made.

I thank members of the Dallas Zoo's Department of Herpetology for help with the preparation of this note.

Submitted by **MATTHEW J. RUSSELL**, Department of Reptiles and Amphibians, Dallas Zoo, 650 South R.L. Thornton Freeway, Dallas, Texas 75203, USA; e-mail: porthidium@aol.com. Present address: Department of Biology, University of Texas at Arlington, Box 19498, Arlington, Texas 76019-0498, USA.

CHIRONIUS FLAVOLINEATUS (NCN)**. COURTSHIP**. The reproductive behavior of Neotropical snakes in the wild is poorly documented. Here, we report courtship involving one adult female *Chironius flavolineatus* (SVL 875 mm, Museu de Zoologia João Moojen de Oliveira, Universidade Federal de Viçosa, MZUFV 943), and six adult males (SVL 700–790 mm, MZUFV 944–946 and Museu Nacional, Universidade Federal do Rio de Janeiro, MNRJ 6453–6455). The animals were found on the ground, at 1800 h on 8 October 1997 in gallery forest (15°09'S, 44°08'W) close to the Mocambinho River, Jaíba, Minas Gerais, Brazil. The snakes were found during the tactile-chase phase of courtship (Gillingham 1986. *In* Seigel et al. [eds.], Snakes: Ecology and Evolutionary Biology, pp. 184–209. McGraw Hill, New York). At any time, two males were in close contact with the female; the remaining males were perched on the ground or in low bushes nearby (Fig. 1). From time to time, males would trade places, so that each male spent time in direct contact with the female and perched nearby. Typically, a male in direct contact with the female would be interrupted by another male that would pull the former out of position. Despite these displacements, males did not engage in combat or any other aggressive behavior. After 30 minutes of observation, we interrupted this behavior because the female appeared stressed and tried to escape. During the observation, we noted the following behaviors: dorsal body looping, chin rubbing, and dorsal advance (Gillingham, *op. cit.*). The latter phases of the courtship act (tactile-alignment, intromission, and coitus) were not observed.

We thank U. Caramaschi and J. P. Pombal, Jr. for commenting on the manuscript and CODEVASF, SYTEC 3, CNPq, FAPERJ, and FUJB for providing financial support.

CHIRONIUS MULTIVENTRIS FOVEATUS (NCN). **PREY.** Existing data on the diet of the colubrid *Chironius multiventris* suggest that, like other members of the genus, it feeds mainly on anurans (especially hylids and leptodactylids; e.g., Cunha and Nascimento 1993. Bol. Mus. Paraense Emílio Goeldi 9:1–191; Dixon et al. 1993. Revision of the Neotropical Snake Genus *Chironius* Fitzinger. Monografie XII, Museo Regionale di Scienze Naturali Torino. 279 pp.). The Atlantic Rainforest subspecies, *C. m. foveatus*, has been reported to prey on the hylids *Osteocephalus langsdorffi* and *Hyla* cf. *hylax* (Marques 1998. Composição Faunística, História Natural e Ecologia de Serpentes da Mata Atlântica, na Região da Estação Ecológica Juréia-Itatins, São Paulo, SP. Ph.D. Dissertation. Univ. de São Paulo. 135 pp.). Hylids of the genera *Hyla* and *Phrynohyas* and leptodactylids of the genera *Leptodactylus* and *Eleutherodactylus*, as well as lizards (genera *Ameiva*, *Anolis* and *Polychrus*) have also been reported as prey of other subspecies of *C. multiventris* (Cunha and Nascimento 1993, *op. cit.*; Dixon et al. 1993, *op. cit.*). Here we report the stomach contents of a specimen of *C. m. foveatus*, a subspecies whose natural history is still largely unknown (Dixon et al. 1993, *op. cit.*).

On 8 December 1996 at 0948 h, on an overcast rainy day, an adult male *C. m. foveatus* (129 cm SVL) was captured by CFDR in an undisturbed Atlantic Rainforest area (ca. 240 m elevation) on the coastal island of Ilha Grande (23°15'S; 44°15'W), near Vila Dios

Rios. The snake, which was moving over large boulders near a subterranean stream (width ca. 5 m), had a slight bulge in its abdomen. Upon dissection and examination of the snake's stomach contents, we found a partially digested, egg-laden female *Hyla circumdata* (Hylidae), the partially digested right hind foot of an adult *Proceratophrys appendiculata* (Leptodactylidae), and numerous insect remains (almost certainly secondary ingestions, originally in the frogs' stomachs). The *H. circumdata* (75 mm SVL) had been ingested head first and the head and trunk were already much digested, though the hind legs were almost intact.

This report confirms the tendency of *C. multiventris* to prey mainly on hylids and leptodactylids and adds a new anuran genus (*Proceratophrys*) and two new species to its diet. The snake (along with stomach contents) was deposited at the Museu Nacional do Rio de Janeiro (MNRJ 6717).

We thank José P. Pombal, Jr., Renato N. Feio, and Marcelo F. Nápoli for identifying the frog remains, and Thais S. de Freitas for confirming the identification of the snake and for her help in taking the measurements. CFDR (Process # 300819/94-3), DV (Process # 143607/98-7), and MVS (Process # 301117/95-0) benefitted from research grants from the Conselho Nacional do Desesnvolvimento Científico e Tecnológico (CNPq).

CROTALUS WILLARDI (Ridgenose Rattlesnake). **MAXIMUM LENGTH**. Stebbins (1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin, Boston, Massachusetts. 336 pp.) reported *Crotalus willardi* reaches 640 mm total length (TL). Lowe et al. (1986. The Venomous Reptiles of Arizona. Arizona Game and Fish Department, Phoenix, Arizona. 115 pp.) reported an upper adult size of ca. 610 mm TL (reported as "exceptionally 24 inches"). Boundy (1995. Bull. Chicago Herpetol. Soc. 306:109–122) reported the maximum length as 641 mm TL based on a specimen of *C. w. obscurus* at the University of New Mexico (MSB 13715) originally reported by Harris and Simmons (1976. Bull. Maryland Herpetol. Soc. 12:1–22). In captivity, *C. willardi* has reached 670 mm TL (Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Comstock Publishing Associates, Ithaca, New York. 425 pp.).

On 23 Sept 1994, we collected an adult male *C. w. obscurus* near the summit of Indian Peak (2585 m) in the Animas Mountains, Hidalgo County, New Mexico. The specimen's mass was 218 g (209 g after defecating) and it measured 668 mm TL (601 mm SVL). This is the largest wild-caught *C. willardi* reported. Since 1994, three additional males exceeding 640 mm TL have been observed on Animas Mountain including: 645 mm on 16 July 1997, 649 mm on 8 October 1996, and 649 mm 7 October 1998.

ELAPHE GUTTATA GUTTATA (Corn Snake). **AGONISTIC INTERACTIONS WITH POTENTIAL PREY.** Maternal aggression towards conspecifics functions to prevent infanticide in *Peromyscus leucopus* (Wolff 1985. J. Mammal. 33:117–123). I have observed this aggression to also be directed towards neonate corn snakes (*Elaphe guttata*) that pose a similar threat to a mother mouse's offspring. In October 1995, the carcass of a captive neonate corn snake that had escaped from its container was found in an adjacent room in the Bowling Green State University Animal Care Facility in a laboratory mouse container housing a female *P. leucopus* and her young. The body of the snake was badly mangled and had numerous bite marks along its length. This incident demonstrated that lactating white-footed mice will react aggressively towards smaller snakes, and indeed are capable of killing them.

To further examine the agonistic interactions between corn snakes and white-footed mice, I conducted controlled arena studies individually pairing six neonate corn snakes (SVL 220–252 mm) with either a lactating *P. leucopus* and her young (two trials), an adult male *P. leucopus* (two trials), or adult female *P. leucopus* (two trials). All of the snakes had been purchased from a supplier, and the mice were wild-caught near Bowling Green, Ohio. The snake and mouse were placed together in a laboratory mouse container (30 x 21 x 13 cm) covered with clear plexiglas, and the container placed on the floor beneath a video camera. A gap between the plexiglas and the container allowed the snake to escape the arena at any point during the trial. Three of the four snakes paired with adult male or female mice attempted to strike the mouse, even though it was far too large to be successfully ingested by the snake. In all instances, the mouse dodged the strike, fled to the opposite side of the container, and never retaliated against the snake. In one of the two trials pairing a neonate snake and a lactating mouse and her young, the snake attempted to strike at the mother and her offspring, but was quickly attacked and bitten by the mother. The trial was immediately terminated, but even in this short exchange the snake suffered a bleeding cut on its ventral side. The snakes and mice used in these tests suffered no permanent harm, and all were healthy afterwards.

It is not known if lactating white-footed mice will react similarly to smaller, foraging corn snakes in the wild, but these observations suggest maternal aggression may influence prey choice in small corn snakes. Although neonate corn snakes will readily eat baby mice in captivity, the diet of wild snakes of the same size consists primarily of lizards and caterpillars, with a shift to predominantly rodent prey with increasing snake size (Hamilton and Pollack 1956. Ecology 37:519–526). If maternal aggression functions to prevent neonate snakes from preying upon baby *P. leucopus* mice in the wild, then ontogenetic diet shifts in snakes may not only be a function of increasing gape size (Mushinsky et al. 1982. Ecology 63:1624–1629), but could also be due to agonistic interactions with potential prey.

Submitted by **MATTHEW M. LAPOSATA**, Department of Biological Sciences, Bowling Green State University, Bowling Green, Ohio 43403, USA. Present address: Department of Biology, The Pennsylvania State University, University Park, Pennsylvania 16802, USA (e-mail: mml146@psu.edu).

ELAPHE OBSOLETA SPILOIDES (Gray Rat Snake). **REPRODUCTION**. Female *Elaphe obsoleta obsoleta* have

clutches of 6–44 eggs, but clutches exceeding 24 eggs are rare (Fitch 1963. Copeia 1963:649–658; Wright and Wright 1957. Handbook of Snakes of the United States and Canada. Cornell Univ. Press, Ithaca, New York. 561 pp.). Although information concerning clutch size and husbandry is available for captive *E. o. spiloides* (Merker and Merker 1995. Reptiles 3:56–75; Staszko and Walls 1994. Rat Snakes. TFH Publications, Neptune City, New Jersey. 208 pp), little is known about the reproductive biology of wild individuals of this subspecies. I report the clutch size of *E. o. spiloides* in Shelby County, Tennessee, USA, at the northwestern extreme of their range (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). During 1994–1997, two clutches were obtained from females that were gravid when collected in the field, and one clutch was discovered in a rotting tree stump. Mass (± 0.5 g) and SVL (± 0.5 cm) were recorded for each female at the time of collection. One female (772.7 g, 124.5 cm) laid 19 eggs and weighed 523.2 g following oviposition. The other female (716.5 g, 122.0 cm) laid eight eggs and weighed 583.4 g following oviposition. Eggs were weighed within 5 h of oviposition; individual egg mass ranged from 10.12–21.74 g (mean ± SE = 13.51 ± 0.68). Relative clutch mass (Shine 1980. Oecologia 46:92–100) averaged 33.42 ± 8.37%.

The clutch found in the tree stump contained eight eggs positioned ca. 75 cm above ground level in a tree stump measuring 25 cm in basal diameter. Activity by a colony of carpenter ants (*Camponotus* sp.) higher in the stump had encased the snake eggs in a layer of decaying wood grains.

Following either collection or oviposition, eggs were incubated at 26–28°C in plastic boxes containing a 1:2 water:vermiculite (by mass) substrate. Eggs hatched between 30 August and 24 September following an incubation period of 60–62 days. Eleven of the 41 eggs (26.8%) failed to hatch or produced still-born embryos following pipping. The sex ratio of the surviving neonates was 1:1.22 female:male.

I thank Tom Norman, Jr. and Dave Frederick for assistance in the field, and Bill Gutzke for comments on the manuscript.

EUNECTES MURINUS (Green Anaconda). **CAIMAN PREDATION**. The green anaconda (*Eunectes murinus*) and the spectacled caiman (*Caiman crocodilus*) are two large predators that use very similar habitats in the seasonally flooded savannas of South America. Predation of caimans by anacondas has been reported (Wehekind 1955. Brit. J. Herpetol. 2:9–13) and appears to occur often in the llanos (Rivas, unpubl. data). Predation by *Caiman sclerops* on *Eunectes notaeus* has been reported (Medem 1983. Los Crocodylia de Suramerica II. Editorial Carrera, Bogota, Colombia. 270 pp.); however, there are no reports of predation by caiman on the larger *E. murinus*. During a seven-year study of the behavioral ecology of the anaconda in the Venezuelan Llanos, we observed spectacled caimans preying on *E. murinus* on three occasions.

On 25 May 1996 we discovered a large caiman (SVL >90 cm) firmly gripping the head of a radio-implanted female anaconda (494 cm total length, 29 kg), who in turn had wrapped herself around the caiman's head and neck. After ca. 15 min. the snake relaxed her coils, apparently losing the struggle with the caiman. When the snake stopped struggling, we interrupted the event to recover the transmitter. Because this snake had been found severely wounded two months before this observation, it is likely that she was not in top physical shape, and this may have played some role in the attack.

Another observation took place on 29 April 1996 in a roadside channel covered partially by water hyacinth (*Eichhornia*). A caiman (SVL >90 cm) was on the left side of the anaconda, gripping it by the anterior 1/5 of its body. The snake had thrown a loop over the dorsal surface of the caiman and wrapped its posterior body and tail around the caiman's left hind leg. The snake, although much smaller than the caiman, was wrapped so tightly around the hind leg that the head of the caiman was pulled towards its hindquarters. The snake periodically tightened its loop, causing the caiman to flip over to the right and under the water. The caiman repeatedly attempted to drag the snake out of the water, but each time the anaconda managed to flip the caiman and pull it back under water. The wrestling match continued for five hours, often punctuated by both animals submerging for periods of 10–15 min. Finally, as the light faded (1900 h), we saw an unidentified caiman of similar size leaving the area with no snake in its mouth. Five days later we found a dead male anaconda (247 cm total length, 5.5 kg), with wounds from a caiman bite on the anterior 1/5 of its body. The wounds suggest a caiman with estimated measurements of 121 cm SVL, 43 kg mass, and 29.5 cm skull length (Thorbjarnarson, unpubl. data). The snake showed no signs of decomposition, indicating a recent death. We surmise that the snake escaped from the caiman but subsequently died from its wounds. Judging by the relationship of masses, we believe that it was the caiman trying to eat the snake and not vice-versa.

The last observation (19 March 1997) also involved a large caiman (SVL >90 cm) attacking a small female anaconda (152 cm total length, 1.7 kg). The caiman was in a small roadside pool with the snake in its mouth. Upon our approach, the caiman dropped the seriously wounded female anaconda. Although the snake survived, we consider this a predation event because the snake was not struggling when we arrived and thus would not have survived without our intervention.

In total, we have found twelve dead anacondas (six males and six females) during the study. Based on our observations and examination of the anacondas (presence of deep circular bite marks matching the size and position of caiman teeth), we determined that all six males and two of the females were killed by spectacled caimans. Interactions between these two sympatric reptiles seem to be quite common.

We are in debt to M. Quero and P Azuaje for their cooperation with the project. W. Holmstrom helped in the data collection and P. Calle was great help in the implantation of the transmitters. We also thank P. Andreadis and G. M. Burghardt for editorial comments on early versions of the manuscript. This research was possible thanks to grants from The Wildlife Conservation Society, The National Geographic Society, CITES, and the Venezuela Fish and Wildlife Service (Profauna). We thank COVEGAN for allowing us to work on their ranch and for all their cooperation with this project.

IMANTODES CENCHOA (Chunk-headed Toad Snake). **AGGREGATION.** Aggregation is a poorly known behavior in snakes. Here we report an aggregation of *Imantodes cenchoa* in the southeastern Peruvian rainforest (Zona Reservada Tambopata-Candamo, Madre de Dios, Perú, 12°51'10"S, 69°21'57"W). On 21 May 1998 at ca. 2000 h, six individual *I. cenchoa* (4 male, 2 female) were observed actively moving in a single plant 1.5–2.5 m above the ground. All individuals were captured by hand, weighed, and measured. The females measured 63.0 cm SVL, 13.5 g; and 71.1 cm SVL, 16.5 g. The males measured 79.2 cm SVL, 20.5 g; 70.2 cm SVL, 16.0 g; 70.9 cm SVL, 20.0 g; and 78.0 cm SVL, 18.0 g. All individuals were adults and neither of the females was gravid. The snakes were subsequently released at the point of capture. We found no obvious purpose for this aggregation.

We thank Chris Kirkby, Huw Lloyd, Arturo Cornejo F., Arturo Palomino M., James I. Watling, and all of our field assistants.

LEPTODEIRA ANNULATA (Culebra Desteñida, Banded Cat-eyed Snake). **DIET**. Colubrids are known to take a wide range of food items, including carrion such as fish (Norton 1993. Herpetol. Rev. 29:34) and frogs (Bedford 1991. Herpetofauna 21:35–36).

Leptodeira annulata is a medium-sized, nocturnal, colubrid snake with a maximum recorded total length of 870 mm (Wilson and Meyer 1985. The Snakes of Honduras. 2nd. ed. Milwaukee Publ. Mus. Publ., Biol. & Geol. No. 6, 159 pp.). This snake feeds on lizards, salamanders, and frogs (Alvarez del Toro 1982. Los Reptiles de Chiapas. 3d ed. Instituto Zoológico del Estado, Tuxtla Gutiérrez, México. 178 pp.). On 11 November 1997 (2250 h) we observed a *L. annulata* (SVL 459 mm) eating a road-killed frog from the gravel road surface in Palo Verde National Park, Guanacaste Province, NW Costa Rica (10°21'N, 85°2'W). The snake was deposited in the Museo de Zoología Universidad de Costa Rica (MZUCR 13629). The frog was in an advanced stage of decomposition, with a strong rotten smell. The snake was peeling the squashed frog from the mud, and subsequent dissection of the snake showed that it had consumed some of the remains. It had rained from 2130 h to 2200 h, and frog activity was high in the area where we found the snake. All the frogs we observed (at least 10 individuals) on the road during the 15 min. prior to the observation were *Rana vaillanti*. Because of similarities in size, we infer that the dead frog may have been another *R. vaillanti.*

These observations were conducted during a field trip of the Zoology II course of the School of Biology, University of Costa Rica. I acknowledge the enthusiasm of my students on this field trip. I thank Gerardo Chaves for the verification of the identification of the snake and frogs, and M. I. Di Mare and W. Eberhard for their suggestions on the ms.

MORELIA AMETHISTINA (Australian Scrub Python). **MALE-MALE COMBAT**. There is considerable diversity among snake species in terms of whether or not males engage in physical combat during the breeding season; and if they do, whether or not the combat bouts involve biting as well as "wrestling" (Shine 1994. Copeia 1994:326–346). Australian pythons of the genus *Morelia* are of particular interest because they include the only recorded case of intraspecific variation in the occurrence of male-male combat. Males display vigorous combat in some populations of *M. spilota*, but not in others (Shine and Fitzgerald 1995. Oecologia 103:490–498). Because the same phenomenon might occur in other *Morelia*, we need records of snake behavior from throughout the range of all species. Combat has been reported in captive specimens of *M. amethistina* (Ross and Marzec 1990. The Reproductive Biology of Pythons and Boas. Institute for Herpetological Research, Stanford, California. 270 pp.), but without detail. Khorzov et al (1995. Russian J. Herpetol. 2:69–70) noted that males of the Indonesian subspecies (*M. a. amethistina*) may bite each other and cause severe injury. Scars on adult male *M. amethistina* in the field in northern Queensland have been interpreted as evidence of male-male combat (Anonymous 1993. Chondro 1:11–12).

One of us (LS) observed and photographed combat between two large scrub pythons one morning (1015 h) in early July 1997, in tropical Queensland (on the outskirts of the town of Gordonvale, near the Mulgrave River). Scrub pythons (*M. a. kinghorni*) regularly inhabit the ceilings of a farmhouse and adjacent shed, especially during winter. Alerted by the sound of items falling from the rafters of the shed, LS found two large (ca. 4.5 m) scrub pythons intertwined, having fallen from the rafters above. The snakes wrestled with each other for ca. 30 min., moving out of the shed and across the adjacent garden area. The posture adopted was similar to that depicted in photographs of male *M. spilota* in combat (see Shine and Fitzgerald, *op. cit.*; and Greer 1998. The Biology and Evolution of Australian Snakes. Surrey-Beatty, Sydney, New South Wales. 358 pp.); the posterior bodies were entwined and the heads of both snakes raised up to 1 m above the ground. One snake repeatedly bit the forebody of the other animal, leaving deep lacerations. The snakes were very similar in size; we infer that both were males. One of the snakes eventually moved away into thick bush; the other (with open wounds from the bites it had received) climbed to the roof of the house, and then to the rafters of the shed where the bout had commenced. Another scrub python (4 m long, without scars, and thus inferred to be female) was coiled among these rafters throughout the combat episode.

This appears to be the first report of male-male combat in free-ranging scrub pythons. Our observations suggest that combat takes the same form in these giant snakes as in other large python species, including other *Morelia* (for a review, see Shine 1994, *op. cit.*). However, our report also provides another example of a puzzling phenomenon first reported for populations of *M. spilota* from northeastern New South Wales (Shine and Fitzgerald, *op. cit.*): the co-occurrence of male-male combat and large mating aggregations within single taxa. Scrub pythons gather in considerable numbers in open areas during the winter mating season in northeastern Queensland, and male-male tolerance rather than aggression has been reported under these circumstances (see page 72 in Shine 1991. Australian Snakes. Reed Books, Sydney, New South Wales. 223 pp. for a photograph of multiple snakes in close proximity). The fact that males tolerate each other sometimes, but battle vigorously at other times, suggests that the reproductive "tactics" of male pythons may be more flexible than has hitherto been assumed.

MORELIA SPILOTA (Australian Carpet Python) **CAUDAL LURING**. Snakes of several phylogenetic lineages utilize caudal

luring to attract prey. Caudal luring involves a snake waving its tail tip such that it resembles a live worm or insect, inducing the potential prey item to approach the snake (Heatwole and Davidson 1976. Herpetologica 32:332–336). Caudal luring appears to be most common in "ambush" predators, such as viperids, boids, and pythonids (Strimple 1995. Litteratura Serpentium 15:74–77). Caudal luring seems to be elicited more easily in juveniles than in conspecific adult snakes (Allen 1949. Copeia 1949:225–226; Rabatsky and Farrell 1996. J. Herpetol. 30:558–561).

Among pythons, caudal luring has been reported in two Australian species: the highly arboreal *Morelia viridis* (Greene and Campbell 1982. Herpetologica 28:32–34) and the semifossorial *Aspidites ramsayi* (Wilson and Knowles 1988. Australia's Reptiles: A Photographic Reference to the Terrestrial Reptiles of Australia. Collins, Sydney. 447 pp.). We can now add another species to this list. We observed and filmed caudal luring in a young (49-day-old) *Morelia spilota mcdowelli* (coastal carpet python) hatched in captivity. The snake's parents were collected near the town of Bellingen on the northern coast of New South Wales, in eastern Australia. While filming for a documentary on python biology on 2 March 1996, one of us (PS) placed a green tree frog (*Litoria caerulea*) in a hexagonal cage (90 cm across) that contained two hatchling pythons. One snake that was loosely coiled on branches several cm above the ground immediately oriented towards the frog and began twitching its tail-tip rapidly. The tail-tip was vibrated a total of 23 times over the course of the next several hours. The first 17 of these vibrations occurred with the tail held >2 cm above the head. The snake then raised its tail above the head and completed six more vibrations.

We used frame-by-frame analysis of the film to quantify several attributes of the tail-flicks exhibited. All of the tail-flicks initiated from beneath the snake's head were horizontal, whereas the tail-tip moved vertically in four of the six "above-head" tail-flicks. These proportions differed significantly ($c^2 = 9.47$, 1 df, $P < 0.003$ with Yate's correction). "Above-head" versus "below-head" flicks did not differ significantly in terms of the arc over which the tail-tip travelled on each tail-flick (respective means ± SD = 91.3 ± 62.5° vs. 77.9 ± 33.4°, ANOVA $F_{1,21} = 0.39$, $P = 0.54$), the total duration of the flick (1.09 ± 0.32 s vs. 0.78 ± 0.34 s, ANOVA $F_{1,21} = 2.90$, $P = 0.10$) or the delay between successive flicks (2.08 ± 2.32 s vs. 1.48 ± 0.64 s, ANOVA $F_{1,21} = 0.87$, $P = 0.37$). However, above-head flicks involved a much greater proportion of the total tail length (27.5 ± 2.9% versus 15.3 ± 8.1%, ANOVA $F_{1,21} = 8.24$, $P < 0.01$). The frog showed no overt response to the snake's behavior, but was later seized and consumed by the snake. Part of this film sequence was included in the completed film ("Python, The Sly Strangler." Roger Whittaker Films Pty Ltd.).

The caudal luring exhibited by this young carpet python was very similar to that seen in other snakes that exhibit caudal luring, including elapids (Carpenter et al. 1978. J. Herpetol. 12:574–577) and viperids (Heatwole and Davidson, *op. cit.*) as well as other pythonids (Rabatsky and Farrell, *op. cit.*). The potential selective advantage of this behavior to cryptic "sit-and-wait" predators is obvious: it may substantially increase the number of potential prey items that approach the snake closely enough to be seized. Juvenile carpet pythons have a diverse diet, although anurans appear to be taken only rarely (Shine and Slip 1990. Herpetologica 46:283–290; Shine and Fitzgerald 1996. Biol. Conserv. 76:113–122). The most surprising aspect of our report is that this distinctive behavior has not been reported previously, because the species involved is abundant, widely-distributed, well-studied in the field and commonly maintained and bred in captivity (Barker and Barker 1994. Pythons of the World. Volume 1, Australia. Advanced Vivarium Systems, Lakeside, California. 171 pp.).

NERODIA TAXISPILOTA (Brown Water Snake). **FEEDING BEHAVIOR**. *Nerodia taxispilota* is known to feed on a variety of fish species that collectively occupy all levels of the water column (Camp et al. 1980. J. Herpetol. 14:301–304; Mills and Hudson 1995. Herpetol. Rev. 26:149). Carr (1940. Univ. Florida Publ. Biol. Sci. Ser. 3:1–118) regarded *N. taxispilota* as probably the fastest swimmer among Florida water snakes, and Camp et al. (1980, *op. cit.*) proposed that speed may allow *N. taxispilota* to capture fish more easily than other *Nerodia*. Here we report an individual *N. taxispilota* hunting fast-swimming, open-water fishes in a ambush fashion.

On 22 April 1998 at 1530 h, a *Nerodia taxispilota*, ca. 1 m total length, was observed for 15 min as it attempted to ambush fish in the Hillsborough River, Hillsborough County, Florida, USA. The snake's tail was anchored to a mat of aquatic vegetation, while its anterior half was extended horizontally from the vegetation. The surface of the water was ca. 10 cm above the snake and the overall depth of the water was 1.5 m. The snake was 5 m from the shoreline and within 2 m of several cypress trees.

Twenty-two fish of the genus *Lepomis* (sunfish) were swimming near and around the snake's head, in some cases within 2–3 cm. The snake's underwater tongue flicks occurred at a rate of 10–12 per minute during five minutes of counting. The snake surfaced for air twice during the observation. On three separate occasions, when the fish swam within 1 cm of the snake's head, the snake struck open-mouthed and made three swift side swipes at the fish. Although no captures were observed, an object approximately the size of a sunfish could be seen moving posteriorly inside the snake's neck, probably indicating recently ingested prey.

Our observation suggests that *N. taxispilota* need not be a fast swimmer to capture fish, and that *N. taxispilota* sometimes hunts fast-swimming, open-water fishes using an ambush strategy.

We thank Ardell Mitchell for reviewing this note.

PSEUSTES SULPHUREUS SULPHUREUS (Papa-Ovo). **DIET**. On 5 September 1998, a specimen of *Pseustes sulphureus sulphureus* was collected in the National Forest of Caxiuanã, Melgaço, Pará State, Brazil. The specimen was captured on the roof of a house after it had eaten a bat, ca. 0300 h. This snake was deposited in the Museu Paraense Emílio Goeldi, Brazil (MPEG 19408). When we examined the stomach of the snake, we found the bat, an adult male *Molossus mollosus* (MPEG 26338). The literature suggests that *P. sulphureus* eats mainly rodents, wild birds, and young domestic animals (Beebe 1946. Zoologica, Chicago, 31[1-3]:11–52; Cunha and Nascimento 1993. Bol. Mus. Para. Emílio Goeldi 9:92–93). We believe that this is the first record of *P. sulphureus* eating a bat.

We thank N. Saldanha for identifying the bat and F. Diniz for suggestions on the manuscript.

SPILOTES PULLATUS (Tiger Ratsnake). **PREY**. Few data are available on the feeding habits of *Spilotes pullatus* (Colubridae) in the wild. On 10 February 1998 (1100 h) at Volcán Mombacho (ca. 1 km SW of Cutirre, 11°49.67'N, 85°56.37'W, 390 m elevation), Departamento de Granada, Nicaragua, we discovered an adult male *S. pullatus* trying to swallow a juvenile Mexican porcupine (*Sphiggerus mexicanus*) (Fig. 1). The locality is at the edge of a coffee plantation close to a forest. Immediately after we found the snake, it started to regurgitate its prey. Both the snake and the porcupine were preserved and deposited in the collection of the Forschungsinstitut und Naturmuseum Senckenberg, Frankfurt, Germany (SMF). The snake (SMF 78370) had a SVL of 160 cm and a tail length (TL) of 57.5 cm. The porcupine (SMF 86959) measured 165 mm SVL, 177 TL and 40 mm hind foot length. The oral cavity as well as parts of body and tail of the snake were spiked with numerous porcupine spines.

We thank Milton G. Camacho, Mauricio Fonseca Cuevas, Carlos Peres-Román, and Sandra Tijerino, Ministerio del Ambiente y los Recursos Naturales (MARENA), Managua, Nicaragua, for granting collecting and export permits, and Gerhard Storch, Forschungsinstitut und Naturmuseum Senckenberg, Frankfurt, Germany, for the identification of the mammal.

THAMNOPHIS ELEGANS VAGRANS (Wandering Garter Snake). **MATING**. The timing of mating in garter snakes is often linked to spring emergence from hibernacula, which may facilitate scramble competition among males for mates (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. University of Oklahoma Press, Norman, Oklahoma. 332 pp.). Here I report observations of spring mating behavior in *Thamnophis elegans vagrans* from a denning area 32 km N of Craig, Moffat Co., Colorado, USA.

On 10 May 1998 at 1400 h I found two *T. e. vagrans* courting in the dirt between sagebrush ca. 10 m from the denning area. The female was 53.5 cm SVL, 69.5 cm total length; the male was 47.5 cm SVL, 63.0 cm total length. Then, at 1600 h I observed three *T. e. vagrans* intertwined at the denning area. I was unable to capture the three snakes to verify sex; however, this behavior is similar to the scramble competition involving one female and multiple males that has been noted at den sites in spring for other populations of *Thamnophis* (Rossman et al., *op. cit.*).

Submitted by **KYLE G. ASHTON**, Department of E.P.O. Biology, Campus Box 334, University of Colorado, Boulder, Colorado 80309, USA (e-mail: ashtonk@colorado.edu).

THAMNOPHIS SAURITUS SAURITUS (Eastern Ribbon Snake). **HIBERNACULUM**. Although information regarding common garter snake (*Thamnophis sirtalis*) hibernacula is relatively abundant (Aleksiuk 1977. Herpetologica 33:98–101; Carpenter 1953. Ecology 34:74–80), such data for the congeneric eastern ribbon snake (*T. sauritus sauritus*) are relatively scarce. Most data available on hibernaculum use by *T. sauritus* are summarized in Ernst and Barbour (1989. Snakes of Eastern North America. George Mason Univ. Press, Fairfax, Virginia, 282 pp.), who reported use of vole tunnels, crayfish burrows, ant mounds, and possibly muskrat (*Ondatra zibethica*) lodges and bank burrows.

On 5 January 1998 amidst a week of unseasonably warm weather, five *T. s. sauritus* were observed at 1245 h on and around a large fallen beech tree (*Fagus grandifolia*) at Mason Neck National Wildlife Refuge, Fairfax County, Virginia, USA. The upturned root base of the tree was situated on a south-facing bank at the northern edge of a permanent tidal marsh with the trunk extending into the marsh. The fallen tree measured ca. 24 m in length and 86 cm in diameter at breast height. The mass of roots and attached soil at the base was 3.5 m in diameter and 98 cm thick. Electronic data loggers placed in the general area to record air temperature at 30 min. intervals indicated that air temperatures had not dipped below freezing the previous two nights, daytime highs had exceeded 16.5°C the previous two days, and mean daily temperatures had exceeded freezing the previous three days. The area surrounding the tree was scrutinized for other possible hibernation sites. None were found, and no snakes other than those around the tree base were found on 5 January.

Of the five *T. s. sauritus* seen on that day, two males were captured. The first (SVL 47.0 cm, mass 37.5 g) had a cloacal temperature of 29.0°C. The second (SVL 43.0 cm, mass 26.0 g) had a cloacal temperature of 26.0°C. The air temperature at the time of the captures was 22.0°C. Two other individuals were entwined on the sunlit bank near the base of the tree, with one exhibiting stimulatory courtship undulations.

We concluded that the ribbon snakes had been overwintering in tunnels, probably created by small mammals, within the tree's upturned root/soil base. The thickness of the root/soil base seemed sufficient to insulate snakes near its center from freezing temperatures. Additionally, the position and southern orientation of the tree base permitted exposure to sunlight at low angles of incidence during most of the winter daylight hours, providing further thermal buffering from frost. This condition is also likely to raise the body temperatures of snakes hibernating within the tree base to the activity threshold more quickly than those hibernating in adjacent soil, resulting in earlier emergence and providing them with an advance choice of amphibian prey.

Submitted by **KERRY A. HANSKNECHT**, **TERRY R. CREQUE**, and **CARL H. ERNST**, Department of Biology, George Mason University, Fairfax, Virginia 22020-4444, USA; e-mail (CHE): cernst@gmu.edu.

HERPETOLOGICAL HUSBANDRY

Notes on the Captive Reproductive Behavior of the Asiatic Four-lined Skink, *Eumeces quadrilineatus*

AKIKO HOSONO
and
TSUTOMU HIKIDA
Department of Zoology, Graduate School of Science, Kyoto University, Kitashirakawa, Sakyo, Kyoto 606-8502 Japan
e-mail (AH): akiko@zoo.zool.kyoto-u.ac.jp

Eumeces quadrilineatus ranges through southern China, Vietnam, Cambodia, and Thailand (Taylor 1935). It has been grouped with the American four-lined forms (*E. gilberti, E. lagunensis,* and *E. skiltonianus*) as the *E. skiltonianus* Species Group (Lieb 1985). Tanner (1957) observed reproduction of *E. skiltonianus* and presented data for the number of eggs per clutch, egg size, and hatchling size in that species. Based on counts of oviducal eggs, Punzo (1982) reported clutch sizes for *E. gilberti* and *E. skiltonianus*. However, there are no published accounts of reproduction in *E. quadrilineatus*. This report, based on captive observations, is the first published information regarding the reproductive traits of this species.

Two females, collected from Cheung Chau Island, Hong Kong, on 25 April 1997, were brought back to our laboratory, labelled #1 and #2, and set up individually in small, round, plastic cages (10 cm [length] x 6 cm [height]) with paper substrate and a water bowl. On 14 May 1997, Female #1 laid one egg with a soft yellowish-white shell, to which she paid no attention. Female #1 and the egg were transferred to a larger transparent plastic rectangular cage (20 cm [length] x 13 cm [width] x 13 cm [height]). Female #2 was also moved to a cage of the same size. Each cage was furnished with 5 cm of soil, a broken flowerpot for shelter, and a water bowl. The soil was moistened with water spray every third or fourth day. Ambient room temperature varied between 23°C and 25°C throughout the observation.

TABLE 1. Measurements (in mm and g) of the females and hatchlings of *Eumeces quadrilineatus*, taken immediately after hatchling. SVL = snout–vent length, HL = head length, HW = head width, TL = tail length, and BM = body mass.

	SVL	HL	HW	TL	BM
Female #1	74.8	13.8	7.8	75	5.02
Female #2	73.2	13.7	7.8	55	5.07
Hatchling #1	25.9	6.3	3.6	36	0.33
Hatchling #2	24.6	5.6	3.7	34	0.30
Hatchling #3	25.1	6.6	3.6	33	0.30
Hatchling #4	24.9	6.5	3.8	35	0.32
Hatchling means	25.1	6.3	3.7	34.5	0.31

Female #1 tunneled from under the shelter to the bottom of the soil and laid a second egg on 17 May. The first egg laid by this female remained on the soil surface and failed to hatch. Female #2 also dug a tunnel and laid three eggs on 18 May. Neither female accepted mealworms or crickets offered as food.

Observations of both females and their eggs were made through the transparent floor of the cages, or by carefully removing the shelters. Both females used their bodies to surround their eggs throughout incubation. Although they occasionally shifted their position within the tunnels, they remained under the soil and never appeared on the surface until their eggs hatched (see below).

When Female #1 was observed outside her tunnel on 27 June, we examined her egg and found a hatchling (Hatchling #1). Female #2 emerged from the soil on 8 July, whereupon we excavated three hatchlings (Hatchlings #2, 3, and 4), while Hatchling #4 was just struggling to extricate itself from its egg. Assuming that the females emerged upon the hatching of their eggs, as is the case of other congeneric species (e.g., *E. elegans*: Kato and Ota 1994), the incubation period of the second egg of Female #1 should be 41 days; the three eggs of Female #2 hatched in 51 days.

Various measurements of adult females and hatchlings are presented in Table 1. Although hatchlings were maintained in the enclosures in which they hatched, all died within three days.

Acknowledgments.—We thank H. Ota and J. Kato for reviewing the manuscript, and S.-L. Chen for collecting the lizards.

NATURAL HISTORY NOTES

The Natural History Notes section is analogous to Geographic Distribution. Preferred notes should 1) focus on observations with little human intrusion; 2) represent more than the isolated documentation of developmental aberrations; and 3) possess a natural history perspective. Individual notes should, with few exceptions, concern only one species, and authors are requested to choose a keyword or short phrase which best describes the nature of their note (e.g., Reproduction, Morphology, Habitat, etc.). Use of figures to illustrate any data is encouraged, but should replace words rather than embellish them. The section's intent is to convey information rather than demonstrate prose. Articles submitted to this section will be reviewed and edited prior to acceptance. Send three copies of manuscripts, double-spaced, directly to the appropriate section co-editor (addresses on inside front cover): J. Brian Hauge (lizards, amphisbaenians, crocodilians, *Sphenodon*); Charles W. Painter (amphibians); or Paul A. Stone (snakes, turtles). Authors are requested to include a 3.5-inch disk containing pertinent files along with hard copy submissions. Indicate disk format (e.g., Macintosh, Windows), word processor name and version used to create the manuscript file, and include a text-only version of the file.

Standard format for this section is as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins (1997. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*, 4th ed., Herp. Circ. 25:1–40; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish*, Herp. Circ. 23:1–113), KEYWORD. DATA on the animal. Place of deposition or intended deposition of specimen(s), and catalog number(s). Then skip a line and close with SUBMITTED BY (give name and address in full—spell out state names—no abbreviations). (NCN) should be used for common name where none is recognized. References may be briefly cited in text (refer to this issue for citation format).

Recommended citation for notes appearing in this section is: Lemos-Espinal, J., and R. E. Ballinger. 1994. *Rhyacosiredon leorae*. Size. Herpetol. Rev. 25:22.

CAUDATA

AMBYSTOMA GRACILE (Northwestern Salamander). **MAXIMUM SIZE.** On 10 February 1998, a neotenic female *Ambystoma gracile* was collected from a wetland bisected by 36th Avenue (T18N R2W NE 1/4 Sec 5), 43 m elev., west Olympia, Thurston Co., Washington, USA. As measured alive (chlorotone anesthetized), the specimen was 106 mm SVL (from tip of snout to anterior end of vent), 228 mm TL (Univ. Michigan FS05406). Leonard et al. (1993. Amphibians of Washington and Oregon. Seattle Audubon Society, Seattle, Washington. 168 pp.) reported the maximum size for neotenic *A. gracile* as ca. 85 mm SVL and 185 mm TL. Nussbaum et al. (1983. Amphibians and Reptiles of the Pacific Northwest. Univ. Idaho Press, Moscow. 332 pp.) reported paedogenetic larvae ranging from ca. 65–105 mm SVL, with the largest individuals being females.

We thank William P. Leonard for confirming the species identification. Funding was provided by the City of Olympia, Department of Planning and Development, Olympia, Washington.

Submitted by **CRIS HAGEN**, 708 Division Street NW, Olympia, Washington 98502, USA, and **CHRISTOPHER R. WILSON**, 4914 Sunset Drive NW, Olympia, Washington 98502, USA.

ANURA

ATELOPUS ZETEKI (Panamanian Golden Frog). **ATTEMPTED PREDATION.** The Panamanian golden frog, *Atelopus zeteki*, is a bufonid found in mid-elevation cloudforests of western-central Panama. The brilliant yellow-orange coloration and high skin toxicity of this frog has made it a prime example of an aposematic species (Duellman and Trueb 1986. Biology of Amphibians. McGraw Hill, New York. 670 pp.). Although snake predation on highly toxic amphibians has been well documented (Noble 1931. The Biology of the Amphibia. McGraw Hill, New York. 577 pp.; Myers et al. 1978. Bull. Am. Mus. Nat. Hist. 161:309-365), there are no records of predation by any species on *A. zeteki*. The following is a description of anti-predator behavior directed at snakes by this frog.

During field studies on this species at Parque Nacional Altos de Campana, Provincia de Panamá in June 1996, an aluminum pole (13 mm diam) was presented by EDL and TEH to three male *A. zeteki* sitting along a stream bank ca. 1 m from the water. All three males showed a dramatic response to this stimulus. Each frog immediately scrambled across the substrate from his original position, dove under water, and remained on the stream floor for up to 12 minutes. This response is in sharp contrast to the slow ambling observed when this species is disturbed by human observers. The marked response to the aluminum pole suggests that the animals were perceiving a potential snake predator.

On 5 December 1997, while making observations on a male *A. zeteki*, EDL and DDB witnessed a predation attempt by an adult snake (ca. 130 cm SVL; genus *Dendrophidion*). Our vantage point was the top of a waterfall looking down on the event and the animals. Our presence appeared to be undetected by the frog and the snake. The interaction was videotaped at 10X magnification on an 8 mm Nikon VN360. Before the encounter, the snake appeared to be actively foraging at the base of the waterfall in the vicinity of the golden frog, which was visible on top of a rock at the stream's edge. The snake was examining rock crevices above and below the water line. When the snake was ca. 10 cm from the frog, the frog moved slightly and the snake struck at the frog. The strike just missed the frog and it rapidly hopped to another rock two feet away from the snake and away from the stream. Then, the frog remained motionless while the snake searched in the immediate vicinity, without finding the frog. Ten minutes later, the snake climbed to a low branch overlooking the area, and remained motionless. At this point, we tried to catch the snake, but failed. Video identification of the genus was confirmed by Roberto Ibáñez of the Smithsonian Tropical Research Institute, Balboa, Panama. The *Dendrophidion* species present at Campana Heights are all very similar in appearance and include *D. nuchalis*, *D. percarinatum*, and *D. vinitor*.

We are grateful for the assistance of A. Stanley Rand, Roberto Ibáñez, César Jamarillo, Frank Solís, and Alberto Castillo. Financial support in part was provided through a Smithsonian Tropical Research Institute short-term graduate fellowship, a Columbus Zoological Park Conservation Fund Grant, a Grant-In-Aid-Of-Research award through Sigma Xi, The Scientific Research Society, and a Graduate School Alumni Research Award through The Ohio State University awarded to EDL.

BUFO MARINUS (Cane Toad). **ENDOPARASITES.** *Bufo marinus* was introduced into Guam from Hawaii in 1937 (Easteal

1981. Biol. J. Linn. Soc. 16:93–113). Herein we report on the helminths from a sample of 27 *B. marinus* (mean SVL 78 mm ± 15.4 SD, range 59–130 mm) collected during 1967, 1971, and 1976–97 from Guam, Mariana Islands. Toads were originally fixed in 10% formalin, later preserved in 70% ethanol, and deposited in the Natural History Museum of Los Angeles County (LACM 144222–144248). The body cavity was opened and the gastrointestinal tract was excised by cutting across the esophagus and rectum. The esophagus, stomach, small intestines, and large intestines were slit longitudinally and examined separately under a dissecting microscope. Each nematode was removed, placed in a drop of glycerol on a glass slide and identified. Trematodes were stained with hematoxylin, mounted in balsam and identified. Two helminths were present: the trematode, *Mesocoelium monas* (Rudolphi 1819), prevalence 52% (13/27); (number infected individuals divided by number of individuals examined) mean intensity 69.6 ± 90.6, range 1–300 (mean number parasites per infected host) and the nematode, *Rhabdias multiproles* Yuen 1965, prevalence 22% (6/27), mean intensity 10.3 ± 8.0, range 1–19. Helminths were deposited in the U.S. National Parasite Museum, Beltsville, Maryland as *Mesocoelium monas* (87755) and *Rhabdias multiproles* (87756). *Bufo marinus* is a new host record for *R. multiproles*.

We thank Richard D. Krizman for providing the sample of *B. marinus*.

PSEUDACRIS TRISERIATA (Western Chorus Frog). **REPRODUCTION**. Few details on characteristics of chorus frog egg masses are published. Reported ranges of the number of eggs per cluster fall are 5–176 (Ruthven et al. 1928. The Herpetology of Michigan. Univ. Michigan Handbook Series. No. 3. ix + 229 pp.; Walker 1946. The Amphibians of Ohio. Part I. The Frogs and Toads. Ohio State Museum of Science. Bull. 1, No. 3. 1–109; Logier 1952. The Frogs, Toads and Salamanders of Eastern Canada. Clarke Irwin, Toronto. xii + 127 pp.; Vogt 1981. Natural History of Reptiles and Amphibians of Wisconsin. Milwaukee Public Museum. 205 pp.; Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State Univ. Press. Baton Rouge. xi + 300 pp.). Vogt (*op. cit.*) reported that egg masses surround grass stems or twigs 7.5–20 cm below the water surface.

We observed recently deposited egg masses in a temporary pond (ca. 1.5 m maximum depth, 30 m^2 area), in savanna habitat at the Ojibway Prairie complex in Windsor, Ontario, Canada (42°25'N, 83°0'N) in late March 1996 (N = 32) and 1997 (N = 36), and early April 1998 (N = 127). Most masses were attached to dead grass stems (e.g., *Phragmites communis*), but some were attached to twigs (*Populus deltoides*, *Quercus palustris*, *Crataegus* spp.) at a mean ± SE water depth (to top of mass) of 11.8 ± 0.56 cm (range 0.5–37 cm). The mean ± SE number of eggs per mass was 63 ± 5.2 (N = 32, range 18–140).

Mean water depth (to top of mass) differed significantly among years (ANOVA, F2, 192 = 133.6, P<0.001) with depth in 1998 (15.8 ± 0.61 cm) being greater than either 1996 (5.3 ± 0.43 cm) or 1997 (3.7 ± 0.38 cm) (Ps<0.001). Differences in depth among years appeared to be related to the amounts of infiltration and/or runoff resulting from precipitation during or after oviposition. In 1998, 41 mm of rain fell in a 24 h period at the site three days prior to our visit. The pond nearly crested its bank and the water depth covering the egg masses increased. The mean depths for 1996 and 1997 would be closer to the actual oviposition depths selected by *P. triseriata* judging by our observations of amplexing pairs. Changing water levels after oviposition would potentially influence larval success by affecting desiccation stress and/or UV-B penetration.

Submitted by **STEPHEN J. HECNAR**, Department of Zoology, University of Guelph, Guelph, Ontario N1G 2W1, Canada, and **DARLENE R. HECNAR**, 74 Janefield Ave, Suite 50, Guelph, Ontario N1G 2L6, Canada.

SCINAX ELAEOCHROA (NCN). **PREDATION**. *Scinax elaeochroa* occurs through the Caribbean lowlands from Nicaragua to western Panama, and in the Pacific lowlands of the Golfo Dulce regions in Costa Rica and Panama (Frost 1985. Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.). On 7 July 1997 at ca. 2300 h, we observed several amplectant pairs of *S. elaeochroa* in a research swamp at La Selva Biological Station, 32 m elev., Heredia Prov., Costa Rica. At 2330 h a male cat-eyed snake (*Leptodeira septentrionalis*), which obviously contained a prey item, was captured near the edge of the swamp.

A sexual pair of *S. elaeochroa*, which had been consumed head first, were palpated from the digestive tract of the *L. septentrionalis*. Although dead, the frogs were still in an amplectant position. After observing several pairs of *S. elaeochroa*, it was noted that the males typically situated their heads around the mid to upper dorsum of the female during amplexus. It would be difficult, if not impossible, for an adult *L. septentrionalis* to restrain both frogs upon first strike. Therefore, it appeared that despite the instant threat of predation the male *S. elaeochroa* did not release his grasp from the female when the snake began feeding.

CROCODYLIA

CAIMAN LATIROSTRIS (Broad-snouted Caiman). **BEHAVIOR.** Tail display is relatively common in vertebrates, but is expressed most dramatically and variably in reptiles. Tail display has been described as an aggressive social behavior in adult males of *Caiman crocodilus crocodilus* during the reproductive period, occurring prior to frontal attack (Azarzaguena 1983. Doñana Acta Vert. 10[3]:1–136). During this display the animal keeps its head and distal portion of the tail arched above the surface of the water. Some head movement may be associated, but this is infrequent.

The same aggressive tail display was directed at me on many occasions by adult (SVL ≥ 75 cm), captive broad-snouted caimans (*C. latirostris*) of both sexes. The display differed in that, after arching their tails above the water, the caimans slowly moved their bodies approximately 45° in relation to the observer, then rotated back to the original frontal position, prior to attack. Frontal attacks would be expected to be faster and more efficient that lateral ones, during which animals would be more vulnerable to counterattack on their flanks. Why, then, does *C. latirostris* apparently compromise its efficiency by turning prior to attack?

One hypothesis is that this position may allow utilization of the tail during attack, but this has never been observed, other than in tail splashing prior to approaching an opponent. Oblique or lateral attacks have never been described. Another possibility may be that the tail acts to distract the opponent from the animal's main weapon, its mouth. If this is true, however, it does not explain why the animal does not rotate a full 90°, which would theoretically maximize the efficiency of the distractive behavior by placing the head and mouth as close to the opponent as the tail.

Perhaps two opposing selective pressures are acting on the same behavior. A frontal position relative to the opponent would favor the attack itself, but would minimize the effect of distractive tail movements. A perpendicular position would maximize distractive effects, but would reduce attack efficiency, as the animal would have to rotate 90° back to the frontal position before attacking. The observed behavior in *C. latirostris* could be the geometric resolution of these two apparently equal selective pressures.

Considering caiman head and tail morphology, tail distractive behavior may be visually efficient only when an opponent's eyes are at water level. It is doubtful that this behavior is part of an elaborate feeding strategy, as caimans are known to be opportunistic predators, and it is unlikely that they developed such complex behavior that would only be of benefit in pursuit of specific prey. Adult crocodilians have almost no natural predators besides humans, and, because tail display in caimans is exhibited only by adults, this behavior is apparently not related to predator defense. By exclusion, the most likely use of tail distractive behavior in caimans is in intraspecific social interactions. Tail displays described by Ayarzaguena (in lit.) for *C. crocodilus crocodilus* dur-

ing reproductive season seem to corroborate this hypothesis.

TESTUDINES

CHELYDRA SERPENTINA (Common Snapping Turtle). **AGGRESSION**. There is an on-going debate about the existence of territoriality in the common snapping turtle (*Chelydra serpentina*). Some researchers have found extensive home range overlap among males (Galbraith et al. 1987. Can. J. Zool. 65:2623–2629), and no evidence of territoriality or aggression (Obbard and Brooks. 1981. Copeia 1981:630–637). Others believe that snapping turtles frequently exhibit intraspecific aggression by defending feeding areas or more simply their immediate surroundings (Kiviat 1980. Trans. Northeast Sect. Wildl. Soc. 37:158–168).

On 28 July 1996, we observed *Chelydra serpentina* biting at the sides of a turtle trap in Grafton Lake, Kejimkujik National Park, Nova Scotia, Canada. Based on their large size, we assumed that both turtles were adult males. For 10 min the turtles chewed at different parts of the trap; each apparently unaware of the other. Both turtles submerged and resurfaced periodically until, at one point they surfaced facing each other ca. 30–40 cm apart. At this point, there was a short (ca. 45 sec) but violent confrontation, with carapaces raised out of the water several times. At the fight's conclusion, one turtle remained near the trap and the second turtle surfaced ca. 40 m from the trap. On inspection the trap was found to contain a live common sucker (*Catostomus commersoni*).

This behavior was similar to an observation made the previous day while radio-tracking two adult males in another part of the lake. For over an hour, the two turtles moved closer to one another, until at one point they were 0.75 m apart. Subsequent tracking five min later revealed that one turtle was still at the site while the other had moved ca. 35 m away. Our unpublished data suggest that snapping turtles, during this time of day (1200 h), generally do not move long distances in such short periods of time. As a result, we suspect that this sudden movement was the result of a confrontation between the two turtles.

These two observations indicate that aggression between snapping turtles does occur. More data are needed before conclusions about the presence/absence of territoriality in this species can be made.

We thank the many participants in the Grafton Watershed Ecological Restoration Monitoring Project, and the staff of Kejimkujik National Park. Support was provided by the Ecosystem Monitoring Fund (Parks Canada) and the Acadia Centre for Wildlife and Conservation Biology.

Submitted by **DONNA D. HURLBURT**, **STEPHEN MOCKFORD**, and **THOMAS B. HERMAN**, Centre for Wildlife and Conservation Biology, Acadia University, Wolfville, Nova Scotia, Canada BOP 1XO; e-mail (TBH): tom.herman@acadiau.ca.

CLEMMYS MUHLENBERGII (Bog Turtle). **OVIPOSITION SITE**. Most *Clemmys muhlenberii* nesting sites have been located within elevated sedge tussocks or sphagnum moss above the water line. However, documented oviposition sites also include the soft soil above springs, adjacent pastures, and the sides of railroad embankments (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington, DC. 578 pp.). On 21 July 1997, a clutch of three eggs (length x width = 30.81 mm x 15.88 mm, 31.42 mm x 15.97 mm, 30.19 mm x 15.85 mm), presumed to be *C. muhlenbergii*, was found ca. 6 cm deep in the top of a rotten, unidentifiable, hardwood stump. The stump, which was partially covered by mosses and poison ivy (*Toxicodendron radicans*), stood ca. 45 cm above the ground and was ca. 35 cm in diameter. All three eggs were collected and incubated at home by one of us (KMF). On 27 August 1997, one of the eggs hatched, confirming their identity as *C. muhlenbergii*. We believe this is the first reported use of a stump for nesting by *C. muhlenbergii*. The remaining two eggs never fully developed and began to rot. The surviving hatchling (30.19 mm CL, 34.41 mm CW; UGAMNH 44225 photo voucher) was released 28 March 1998 at the site of collection.

The collection site, Wolf Creek Bog (Chattahoochee National Forest, Union County, Georgia, USA), was first confirmed to be inhabited by *C. muhlenbergii* in 1979 (Hale and Harris 1980. Herpetol. Rev. 11:14). This bog site has been slowly succeeding to a more closed canopied hardwood forest. As a result, there is increasingly limited sedge and sphagnum moss areas in which to nest, potentially forcing *C. muhlenbergii* at this site to seek alternative oviposition areas. U.S. Forest Service personnel have begun management to reduce the hardwood encroachment and thus open up the canopy. This represents the first recorded nesting of *C. muhlenbergii* in Georgia.

We thank Jim and Cindy Wentworth of the U.S. Forest Service for their dedication to bog turtle conservation within the Chattahoochee National Forest.

Submitted by **KENNETH M. FAHEY**, 439 Pinewood Drive West, Dahlonega, Georgia 30533, USA, and **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john_jensen@mail.dnr.state.ga.us).

DERMOCHELYS CORIACEA (Leatherback Sea Turtle). **ACCIDENTAL CAPTURE**. Records of *Dermochelys coriacea* on the Brazilian coast are rare (Bellini and Sanches 1998. Marine Turtle Newsltr. 79:22; Menezes 1972. Arq. Ciênc. Mar. 12:17–20; Moreno et al. 1994. Anais do II Encontro Sobre Coordenação de Pesquisa e Manejo da Franciscana. Ed. da FURG, Florianópolis, Brasil. 88 pp.). Two leatherback turtles were accidentally caught during fishery prospection near Saint Paul's Rocks, using a 28,000 m oceanic longline with 600 hooks baited with Brazilian sardines (*Sardinella brasiliensis*). A dead juvenile *D. coriacea* of undetermined sex was boarded on 18 October 1996. It measured 40 cm CCL (curved carapace length) and was caught at 180 m depth (00°46'S, 33°18'W). The specimen was photographed onboard and soon thrown overboard. A living adult (CCL = 180 cm) was caught on 19 October 1996. It was probably a female, based on the absence of a long tail, and was at 130 m depth (01°40'S, 33°36'W). The latter, while being boarded, showed a behavior similar to that described by Engrid et al. (1992. Herpetol. Rev. 23:70–71), swimming in wandering movements (zigzag) on its backside. Due to its great size, it could not be boarded, but was instead photographed in the water and released. Color slides of this turtle are on file in the Museu de História Natural, Universidade Estadual de Campinas (no catalog number). These are the northernmost records of the leatherback sea turtle in the Western South Atlantic. Apparently, sea turtle captures in this type of fishery are more common than reported. Artisanal fishermen from the Praia de Itapoã, Salvador, Bahia State (pers. comm. to C. L. S. Sampaio) and from several sites of southern Espirito Santo state (pers. comm. to J. L. Gasparini) report frequent captures of *D. coriacea.*

Many thanks to Ellen Wang and Sérgio R. Floeter for the English version, I. Sazima and J. L. Gasparini for comments on the manuscript, Renato B. Paglerani for colors slides and information about accidental captures, and CNPq for financial support.

Submitted by **CLÁUDIO LUIS S. SAMPAIO**, Universidade Federal da Bahia, Instituto de Biologia, Campus Universitário de Ondina, CEP 40.170-110, Salvador, Bahia, Brazil. Present address: Av. Sete de setembro, 2141/101, Edf. Caiçara, CEP 40.080-002, Salvador, Bahia, Brazil; e-mail: sampaio@ufba.br.

GOPHERUS AGASSIZII (Desert Tortoise). **PREDATION.** A variety of predators, most notably coyotes (*Canis latrans*) and common ravens (*Corvus corax*), have been reported to prey on hatchling desert tortoises, *Gopherus agassizii* (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 578 pp.). Here, we report an observation of a hatchling tortoise, fitted with a radiotransmitter, that was preyed upon by native fire ants (*Solenopsis* sp.) in the eastern Mojave Desert at Yucca Mountain, Nevada (36°50'N, 116°25'E). On 27 August 1993, we found a live, 5 day-old *G. agassizii* (45 mm carapace length) with the eyes, chin, and parts of the head and legs being eaten by ants. The tortoise was lethargic and responded little when touched. The ants were removed, and the tortoise was released near the site of capture. When relocated the next day, the tortoise was dead. This specimen was deposited at University of California at Berkeley, Museum of Vertebrate Zoology (MVZ 223521). Eight of 74 other radiomarked hatchlings (aged 3–7 days) that we monitored during 1992–1994 were found dead with fire ants scavenging the carcasses. We do not know if the ants preyed on these tortoises or if the ants were simply scavenging the carcasses. Five of these specimens were deposited at MVZ (223522, 223524, 223532, 223535–36). Although imported fire ants (*S. invicta*) have long been known to kill hatchling gopher tortoises, *G. polyphemus* (Mount 1981. J. Alabama Acad. Sci. 52:71–78), native fire ants have not been implicated previously as predators of desert tortoises.

Tortoises were handled under permits PRT-683011 and PRT-781234 from the U.S. Fish and Wildlife Service, and S-0446, S-1595, S-3108, S-5041, S-6941, and S-9060 from the Nevada Division of Wildlife. This research was supported and managed by the U.S. Department of Energy, Yucca Mountain Site Characterization Office, as part of the Civilian Radioactive Waste Management Program under contracts DE-AC08-88NV1067, DE-AC08-93NV11267, DE-ACO1-91RW00134, and DE-ACO8-91RW00134.

Submitted by **JAMES L. BOONE**, **DANNY L. RAKESTRAW**, and **KURT R. RAUTENSTRAUCH**, Science Applications International Corporation (SAIC), 1180 Town Center Drive, Las Vegas, Nevada 89134, USA (e-mail for JLB: jim_boone@ymp.gov).

GOPHERUS POLYPHEMUS (Gopher Tortoise). **SCAVENGING.** *Gopherus polyphemus* is an obligate grazer (Garner and Landers 1981. Proc. Conf. Southeast Assoc. Fish Wildl. Agencies 35:120–134; Macdonald and Mushinsky 1988. Herpetologica 44:345–353). Reports of carnivorous scavenging by this species are extremely rare (Garner and Landers, *op. cit.*; Anderson and Herrington 1992. Herpetol. Rev. 23:59). At 1400 h on 3 September 1997, DRJ observed a small adult or subadult gopher tortoise (15 annuli, CL 178 mm, PL 173 mm) scavenging the dry, flattened carcass of a great-horned owl (*Bubo virginianus*) on the edge of Georgia highway 33, 20 km north of Sylvester, Worth County, Georgia, USA. The activity took place in full sun at 33°C, with the tortoise ignoring occasional passing traffic. When handled, the tortoise voided a brownish urine. A voucher slide (UF 113440) has been deposited in the photographic archive of the Herpetology Collection, Florida Museum of Natural History.

In June 1992, TEO observed a juvenile gopher tortoise (130 mm CL) energetically consuming the dried remains of a road-killed armadillo (*Dasypus novemcinctus*) on US highway 19 in Citrus County, Florida, USA, near Crystal River. Old field and native upland pine habitats occurred at both the Georgia and Florida sites.

Scavenging of dried vertebrate remains may facilitate acquisition of minerals, such as calcium and phosphate, that often are poorly represented in the leached, sandy soils typically occupied by this herbivorous turtle (Garner and Landers, *op. cit.*). Our observations underscore the use of this foraging component by demographic groups other than mature females, the group emphasize by Garner and Landers (*op cit.*). In addition to the tortoise's propensity for living along roadsides, which facilitates its collection by humans for food or pets, feeding upon road-killed vertebrates may contribute directly to mortality (from automobile impact) of this already declining species.

We thank Todd Engstrom for identification of the owl carcass.

Submitted by **DALE R. JACKSON**, Florida Natural Areas Inventory, 1018 Thomasville Road, Suite 200-C, Tallahassee, Florida 32303, USA (e-mail: djlcmlcm@aol.com), and **THOMAS E. OSTERTAG**, Department of Biological Sciences, Southeastern Louisiana University, Hammond, Louisiana 70402, USA.

TERRAPENE ORNATA LUTEOLA (Desert Box Turtle). **ATTEMPTED PREDATION.** A wide variety of predators, including birds, are known or suspected of eating eggs or young of turtles (Legler 1960. Univ. Kansas Publ., Mus. Nat. Hist. 11:527–669; Walley 1993. Herpetol. Rev. 24:148–149; Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Inst. Press, Washington, DC. 578 pp.). Predation on adults is less common, although large mammals like coyotes (*Canis latrans*), raccoons (*Procyon lotor*), and skunks (several species) might be capable of killing adults of some species (Harding 1997. Amphibians and

FIG. 1. Photograph taken October 1988 indicating shell damage on a female *Terrapene ornata luteola* inflicted by a turkey vulture (*Carthartes aura*).

FIG. 2. New epidermal material covering the damaged shell in July 1998.

Reptiles of the Great Lakes Region. The University of Michigan Press, Ann Arbor. 378 pp.). Birds are rarely considered predators of adult turtles, although two gulls (*Larus* sp.) attacked an adult *Malaclemys t. terrapin* (Watkins-Colwell and Black 1997. Herpetol. Rev. 28:87–88) and severely damaged the turtle's limbs.

On 3 October 1988 at 1826 h, I saw a turkey vulture (*Carthartes aura*) standing on an adult *Terrapene ornata luteola* on a dirt road in the Sevilleta National Wildlife Refuge, ca. 85 km south of Albuquerque, New Mexico, USA. From a distance I could see the vulture using its beak on the carapace of the turtle. I watched the interaction for ca. 1 min before driving up to the pair. As I drove up, the bird flew off. The turtle had both ends of its plastron shut tightly. The turtle was a female (128 mm carapace length, 480 g) that I had marked in August 1987. At that time, there was no damage to the carapace of the turtle. The carapace was now damaged, and judging from the behavior of the vulture and the fresh appearance of the damage, it seems likely that the damage was caused by the vulture. The vulture had apparently scraped off epidermal lamellae down to bone in one contiguous area on the right front of the carapace (Fig. 1). Although bone was exposed, the turtle did not seem to be seriously injured otherwise. Florida box turtles (*T. carolina bauri*) can survive extensive loss of epidermal material due to fire (Dodd 1997. Herpetol. Nat. Hist. 5:66–72). I do not know how much more damage could have been inflicted on the turtle if the vulture had not flown off when I approached.

I found the turtle again on 9 July 1998 while resurveying the population on the Sevilleta NWR. The damaged area of the shell had completely healed over with new epidermal material (Fig. 2). In addition, this female was carrying two eggs, a further indication of no lasting harm due to the attack.

Submitted by **DAVID J. GERMANO**, Department of Biology, California State University, Bakersfield, California 93311, USA (e-mail: Dgermano@csubak.edu).

LACERTILIA

GALLOTIA SIMONYI MACHADOI (Hierro Giant Lizard). **UNDESCRIBED BEHAVIOR.** The Hierro giant lizard is a diurnal, heliothermic, large lacertid (≤ 226 mm SVL) presently threatened with extinction, as the only remaining population, about 1600 individuals (Rodríguez-Domínguez, unpubl. data), is located in the small overhang of a cliff in the northeastern part of El Hierro Island (Canary Islands). Information regarding reproduction of the species is limited (Rodríguez-Domínguez and Molina-Borja 1998. J. Herpetol. 32:498–504).

The Canary government keeps 57 adult lizards in captivity, six of them captured from the natural habitat, at the Recovery Center for the Hierro giant lizard; they have been the progenitors for a breeding program that began in 1985. Here I report on previously unknown homosexual behavior between males, long-term sperm storage by females, and of the presence of coagulated material on the hemipenes and cloacas of some males and females. None of these features has been previously reported for *Gallotia*.

Observations were made through a blind in a large outdoor terrarium; the observer was 2–7 m from the animals. On 16 July 1997, I introduced four males of similar sizes and allowed them to interact freely. The largest male (226 mm SVL, 357 g mass), throat inflated and performing headbobs, approached another male (207 mm SVL, 288 g mass). The larger male bit the other's neck skin and attempted to insert one of his hemipenes into the other's vent. During that time, the second male struggled and exhibited nervous, vertical head shakings. Finally, the dominant male rubbed the other's back with his hemipenis. The lizards then became aware of the observer's presence and immediately separated and retreated. I saw remains of small stones in the center of the hemipenis's lobe that certified that the organs were everted.

On the other hand, I observed successful hatching of eggs laid by females that had been maintained in terraria without males for one year, indicating that *Gallotia simonyi* females may store living sperm and that fertilization need not immediately follow copulation. These females (N = 10) were born in captivity (mean SVL 184.9 mm, SD 1.9, range 165–192 mm), and included one six-year-old, one eight-year-old, and seven nine-year-old individuals. Clutches were produced from 25 June to 15 July 1997 (mean clutch size 4.11, SD 0.86); however, out of 37 eggs, only five live young hatched, one of which had a malformed backbone and an occluded eye.

During the reproductive period, four males exhibited a coagulated white secretion in the center of one or both lobes of the hemipenes. This material also was observed in the cloacas of two females. Although its appearance is very similar to the mating plugs that have been described in females of some snakes (Devine 1977. Nature 267:345–346), I cannot presently tell if this material has the same composition and function, i.e., to discourage copulation by other males.

I thank Miguel Molina-Borja from the Dpto. de Biología Animal, Facultad de Biología, Universidad de La Laguna (Tererife) and an anonymous reviewer for reviewing the original manuscript.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). **PREDATION**. On 1 September 1997 we collected a young *Hemidactylus turcicus* (0.45 g, 27.8 mm SVL, 34.8 mm TL; UTA R-43562) and an adult female comb-footed spider *Tidarren sisyphoides* (6.9 mm cephalothorax and abdomen length) in its web. The web was discovered on the bottom of an office table within the Bird and Reptile Building at the Dallas Zoo, Dallas County, Texas, USA. The web also contained five spider egg cases, four of which were empty and one that was hatching. When found, the spider was actively feeding on the tip of the mandible of the gecko but retreated when disturbed. The Theridiidae, or comb-footed spiders, build irregular webs and cast viscous silk over their prey. They are known to prey on small lizards (Blondheim and Werner 1989. Brit. Herpetol. Soc. Bull. 30:26–28; McCormick

and Polis 1982. Biol. Rev. 57:29–58; Welter and Fauth 1996. Herpetol. Rev. 27:79) and to subdue prey many times their own size.

Submitted by **DAVID T. ROBERTS** and **RUSTON W. HARTDEGEN**, Dallas Zoo, Department of Herpetology, 650 South R.L. Thornton Freeway, Dallas, Texas 75203-2996, USA, and **DANIEL FORMANOWICZ**, Department of Biology, University of Texas at Arlington, Box 19498, Arlington, Texas, 76019, USA.

LACERTA LEPIDA (Ocellated Lizard). **NECROPHAGIA and OOPHAGIA**. Necrophagia and the consumption of bird eggs are known among large saurian species; however we have found only one explicit reference indicating necrophagia in *Lacerta lepida* (Calderón 1977. Doñana, Act. Vert. 4:61–126) and another implicit one (Hódar et al. 1996. J. Arid Env. 33:95–107). Oophagia in this species has been documented in analyses of the digestive tract and feces (Calderón 1977. *op. cit.*), but as *L. lepida* does not normally ingest eggshells (De Juana and De Juana 1982. Doñana, Act. Vert. 9:374–375), evidence of oophagia may have been overlooked.

On 15 May 1986, at 1300 h, near Constantina (Seville, Spain, UTM 30s TG6995), we observed an adult male *L. lepida* devouring vitellogenic follicles and fat bodies of a recently-roadkilled female conspecific. On 29 May 1986 at 1730 h near the Sanctuary of the Virgen de la Cabeza (Jaén, UTM 30s VH1126), and again on 5 July 1986 at 1010 h in El Dornajo (Granada, UTM30s VG6108), we found an adult *L. lepida* feeding on an adult male Montpellier snake, *Malpolon monspessulanus* (SVL of male 1250 mm, of female 602 mm, respectively), also recently roadkilled. On 20 March 1987 in Tobazo (Jaén, UTM 30s VG0956), we found a roadkilled adult male *L. lepida* with the remains of a female ladder snake, *Elaphe scalaris* (860 mm SVL), in its mouth.

On the sandy escarpment of the palaeocanal of the River Guadalete (C·diz, UTM 30s TF6584), was a small nesting colony of bee-eaters (*Merops apiaster*) with 11 occupied nests. On 6 May 1997 at 1800 h we saw an adult female *L. lepida* emerge from one of the nests with an egg in its jaws. At the entrance of the nest hole, the lizard broke open the egg, devoured the contents and discarded the shell. The lizard re-entered the nest hole, emerged with another egg and repeated the action. Afterwards, the lizard moved over the escarpment and entered a second nest, and this time emerged with a recently-hatched Bee-eater chick; at the entrance of the nest the chick was rapidly swallowed. After ingesting another egg from a third nest, the lizard fled.

SCELOPORUS OCCIDENTALIS LONGIPES (Great Basin Fence Lizard). **PREDATION**. Although birds such as raptors, corvids, cuckoos, and shrikes are well-known predators of reptiles (Terres 1991. The Audubon Society Encyclopedia of North American Birds. Wings Books, New York. 1109 pp.), observations of predation in the wild are relatively scarce. On 23 February 1998, at east Lake Hodges, San Diego County, California, USA (33°03'45"N, 117°03'45"W; elev. 98 m), we observed an adult male great-tailed grackle (*Quiscalus mexicanus*) attack and consume two adult male *Sceloporus occidentalis longipes*. The grackle was perched near shore, searching for prey on a floating western cottonwood (*Populus fremontii*) branch when the first lizard was seized at 0830 h. The lizard was carried about 10 m to a small stand of cat-tail (*Typha angustifolia*) and willow (*Salix* sp.), where the tail and visceral contents were consumed first, followed by the remainder of the lizard's body. Shortly thereafter, at the same feeding site, the grackle seized a second lizard in a clump of dead cat-tails, flew about 50 m to a cottonwood, and again consumed tail and viscera first, followed by head and body.

The winter 1997–98 flooding of Lake Hodges and surrounding riparian woodland has displaced *S. o. longipes* to tree perches and floating vegetation (C. Mahrdt, pers. obs.), greatly exposing this species to avian predators. Although natural predators of *S. occidentalis* include birds and several colubrid snakes (Bell and Price 1996. Cat. Amer. Amphib. Rept. 631.1–631.17; Fitch 1940. Univ. California Publ. Zool. 44:151–172), apparently this is the first reported observation of a great-tailed grackle preying on a western fence lizard.

We thank Kent Beaman for his comments and review of the manuscript.

Submitted by **CLARK R. MAHRDT**, Herpetology Department, San Diego Natural History Museum, P.O. Box 1390, San Diego, California 92112, USA, and **RICHARD L. BARBER**, Palomar Audubon Society, 15569 Walton Heath Row, San Diego, California, USA.

SCELOPORUS VIRGATUS (Striped Plateau Lizard). **PREY**. Although *Sceloporus virgatus* is a relatively well-studied lizard, little is known about its diet beyond that fact that it is insectivorous. I report an attempted predation event by *S. virgatus* on a potentially dangerous prey item, a centipede (species unknown), in a wooded area of a study site in the Chiricahua Mountains (1600 m elev.), approximately 2.5 km SW Southwestern Research Station, Portal, Cochise County, Arizona, USA (see Smith 1996. Amer. Midl. Nat. 135:68–80). On 7 June 1993 I observed a female *S. virgatus* (SVL 53 mm) attack and attempt to consume a relatively large centipede (30–40 mm). The predation attempt by the lizard was unsuccessful, and involved a highly violent interaction, ending when the female released the centipede. The latter subsequently escaped.

TUPINAMBIS MERIANAE (Common Tegu). **ACTIVITY.** Although the genus *Tupinambis* is widely distributed in South America east of the Andes, with species occurring along many ecosystems (Ávila-Pires 1995. Lizards of Brazilian Amazonia [Reptilia: Squamata]. Nationaal Natuurhistorisch Museum, Leiden, The Netherlands. 706 pp.), information on their activity based on field data is scarce. *Tupinambis merianae* occurs in many Brazilian environments such as cerrado, caatinga, and the Atlantic forest. In an area of Atlantic Rainforest at Ilha Grande (23°11'S, 44°12'W), Rio de Janeiro, southeastern Brazil, *T. merianae* is the most abundant species of lizard. Field work was carried out at two sites, (1) a relatively undisturbed forest and, (2) a 30-yr-old regenerated forest. During transects carried out at both sites between January and December 1996, it was common to see and hear active individuals of *T. merianae* foraging and basking, mainly at sunny patches in the forest. The transects were always done between 0700 h and 1700 h. Each time we detected a lizard, we recorded the date and time. The lizards were active between

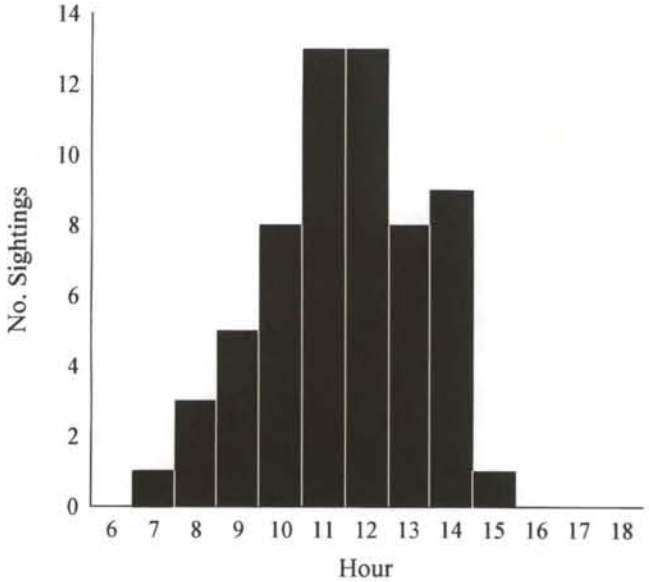

FIG. 1. Daily activity of *Tupinambis merianae* in the Atlantia rainforest of Ilha Grande, Rio de Janeiro, between January and December, 1996.

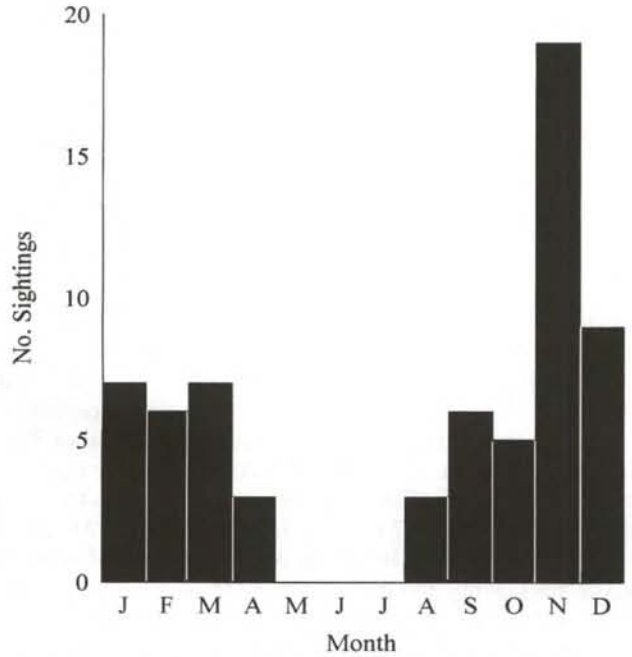

FIG. 2. Number of active *Tupinambis merianae* each month.

0700 h and 1500 h. Daily activity was unimodal, being highest during the hottest period of the day (1100–1300 h, Fig. 1). Yearly activity peaked during November; there was a period of aestivation between May and July (Fig. 2). This pattern of activity is similar to that of *T. teguixin*, at Serra do Japi, an area of Atlantic Rainforest in the State of São Paulo (Sazima and Haddad 1994. *In* Morellato (ed.), História Natural da Serra do Japi, pp. 212–236. EDUNICAMP/FAPESP, Campinas, São Paulo, Brazil). It is also similar to that of two Argentinian species, *T. teguixin* and *T. rufescens*, which overwinter in burrows and become active in September and October (Fitzgerald et al. 1991. *In* Robinson and Redford [eds.], Neotropical Wildlife: Use and Conservation, pp. 303–316. University of Chicago Press, Chicago, Illinois). These species also have a peak of activity during the spring, mainly during November and December (Fitzgerald et al. 1994. Interciencia 19:166–170).

SERPENTES

CLELIA CLELIA (Mussurana). **ATTEMPTED PREDATION.** *Clelia clelia* is a rear-fanged colubrid found at low to moderate elevations from southern Mexico to Argentina. It occurs in all but the driest lowland areas of Costa Rica. Ophiophagy has been well documented in this species, but few observations have been made in the wild (Scott 1983. *In* D.H. Janzen [ed.], Costa Rican Natural History, pp. 392. University of Chicago Press, Chicago, Illinois.).

On 8 July 1997 at 0130 h, we discovered a juvenile *C. clelia* attempting to eat a subadult *Leptodeira septentrionalis* (cat-eyed snake). This observation was made near the edge of a research trail at the La Selva Biological Station, Heredia Province, Costa Rica (32 m elev.). Photographs were taken immediately and 12 minutes of observation followed (Fig. 1). During this time, we sat on the trail with our flashlights dimmed ca. 3 m from the location of the snakes. The *C. clelia* was successively biting at the nuchal region of the *L. septentrionalis* while constricting the anterior and midbody with four tight coils. After 12 minutes, the *C. clelia* aborted the attempted predation and retreated. Surprisingly, despite probable envenomation and suffocation, the *L. septentrionalis* was not immobilized and made a rapid escape. Due to its swift retreat, we could not capture the *L. septentrionalis* for measurements. However, it can be safely stated that the *L. septentrionalis* was greater in length than the *C. clelia*, but not in circumference. The *C. clelia* measured 61.9 cm SVL, 74.9 cm total length, and weighed 68.8 g.

CROTALUS ATROX (Western Diamondback Rattlesnake). **MORPHOLOGY**. Klauber (1972. Rattlesnakes. Their Habits, Life Histories, and Influence on Mankind. Univ. California Press, Berkeley, California. 740 pp.) reported the congenital absence of rattles in three species of rattlesnakes, *Crotalus cerastes*, *C. horridus*, and *C. pricei*. A rattleless form of *C. ruber lorenzoensis* is well established in the population on Isla San Lorenzo del Sur, and *C. catalinensis* has no rattles other than the proximal segment (Campbell and Lamar. 1989. The Venomous Reptiles of Latin America. Cornell Univ. Press, Ithaca, New York. 425 pp.). A captive rattleless *C. v. viridis* gave birth to a single rattleless neonate in a brood of 12 (H. M. Smith, pers. comm.).

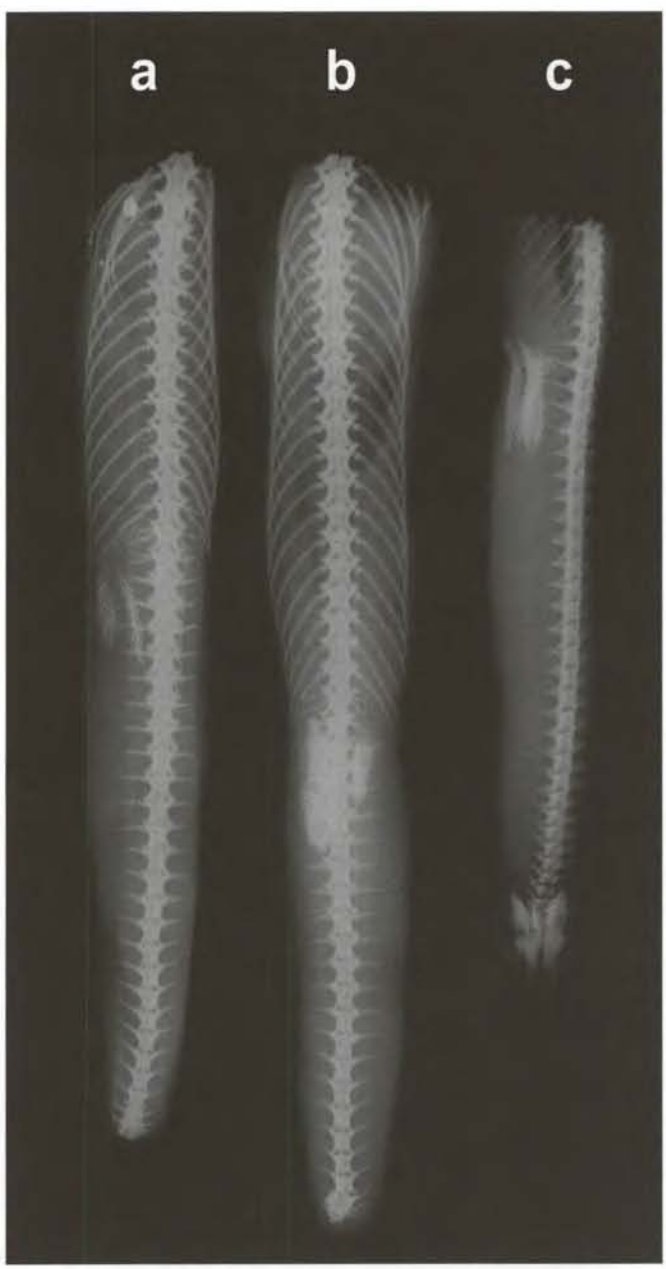

FIG. 1. Radiograph of three *Crotalus atrox*, showing normal tail (left) and congenital absence (middle, right) of rattle segments. All specimens from Eddy Co., New Mexico.

While conducting studies at the 8th annual Rattlesnake Extravaganza in Alamogordo, New Mexico, USA, during April 1995, CWP and LAF obtained two rattleless *C. atrox*. These specimens were collected from a den near Artesia, Eddy Co., New Mexico, on an unspecified date in April 1995. The hunter (anonymous) indicated he had observed other rattleless *C. atrox* in the same area.

The posterior 15 cm of each specimen was removed, X-rayed, and compared with a specimen possessing normal rattles (Fig. 1). The abnormal specimens were examined grossly for evidence of injury and corresponding scar tissue. The radiograph and gross exam revealed no evidence of scar tissue or previous injury, so we conclude that this condition was congenital rather than the result of an injury or removal of the rattles by trophy hunters. This is the first report of this rattleless condition in *C. atrox*. The specimens (MSB 60386-388) are accessioned into the Division of Herpetology, Museum of Southwestern Biology, University of New Mexico.

FITZGERALD**, Texas A & M University, Department Wildlife and Fisheries Sciences, College Station, Texas, 77843-2258, USA, and **MARK L. HEINRICH**, Carlsbad Animal Clinic, 103 East Blodgett, Carlsbad, New Mexico 88220, USA.

CROTALUS LEPIDUS (Rock Rattlesnake), ***CROTALUS MOLOSSUS*** (Blacktail Rattlesnake), ***CROTALUS PRICEI*** (Twin-spotted Rattlesnake), ***CROTALUS TIGRIS*** (Tiger Rattlesnake). **ENDOPARASITES.** There are, to our knowledge, no reports of endoparasites for *Crotalus lepidus, C. pricei* or *C. tigris*. There is one report of a nematode, *Kalicephalus inermis* in *C. molossus* from México (Prado Vera 1971. Thesis, Univ. Nac. Auton. México, D. F. 102 pp.). The purpose of this note is to report the presence of larval tapeworms (cestodes) in *C. molossus* and *C. pricei* and larval spiny-headed worms (acanthocephalans) in *C. lepidus* and *C. tigris*. The body cavities of a total of 55 *C. lepidus* from Arizona, Texas and México, 129 *C. molossus* from Arizona, New Mexico, Texas and México, 40 *C. pricei* from Arizona and México and 117 *C. tigris* from Arizona and México in the herpetology collections of the Natural History Museum of Los Angeles County and the University of Arizona were examined for helminths. A mid-ventral incision was made in the body wall, and organ surfaces and mesenteries in the posterior portion of the body cavity were visually checked for helminths. Oblong whitish bodies, approximately 1 by 3 mm were occasionally seen. These proved upon microscopic examination to be oligacanthorhynchid acanthocephalan cystacanths in *C. lepidus* and *C. tigris*, and tetrathyridia of *Mesocestoides* sp. in *C. molossus* and *C. pricei*. Prevalence of infection (infected snakes/sample examined x 100) was 5% each for oligacanthorhynchid cystacanths in *C. lepidus* and *C. tigris* and 2% and 5% for tetrathyridia of *Mesocestoides* sp. in *C. molossus* and *C. pricei*, respectively. Specimens were deposited in the U.S. National Parasite Collection, Beltsville, MD: oligacanthorhynchid cystacanths, *C. lepidus* (87642), *C. tigris* (87643); tetrathyridia of *Mesocestoides* sp., *C. molossus* (87644), *C. pricei* (87645).

Oligacanthorhynchid cystacanths have been found in other North American crotalids, *Crotalus atrox* and *C. scutulatus* (Bolette 1997. J. Parasitol. 83:751–752; Bolette 1997. Southwest. Nat. 42:232–236). Tetrathyridia of *Mesocestoides* sp. have been reported *C. atrox* and *C. viridis* (Bolette 1997. J. Parasitol. 83:751–

752; Mankau and Widmer 1977. Jap. J. Parasitol. 26:256–259). Rattlesnakes are believed to be paratenic hosts (Bolette *op. cit.*). The presence of oligacanthorhynchid cystacanths in *C. lepidus* and *C. tigris*, and tetrathyridia of *Mesocestoides* sp. in *C. molossus* and *C. pricei* are new host records and represent the first records of helminths in *C. lepidus, C. pricei* and *C. tigris*.

We thank Robert L. Bezy (Natural History Museum of Los Angeles County) and Charles H. Lowe (University of Arizona) for permission to examine *Crotalus lepidus, C. molossus, C. pricei* and *C. tigris* for helminths.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA, e-mail: sgoldberg@whittier.edu, and **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA; e-mail: cxb13@psu.edu.

CROTALUS MOLOSSUS MOLOSSUS (Northern Blacktail Rattlesnake). **BROOD DEFENSE.** An adult *Crotalus molossus molossus* was encountered near Tanque Verde Creek, Reddington Pass, Pima County, Arizona, USA, on a morning in early September 1984 (ca. 8 September). It was crawling toward me while rattling at 5 m distance, and when I stopped, the snake stopped 3 m away. After about 10–15 s, it returned in the direction from which it had crawled, traveling 4 m to an opening at the base of a massive rock outcrop, where it coiled. After a pause of ca. one minute, I approached to within 5 m and the snake again crawled toward me while rattling. When I stopped, the snake stopped about 2 m away, and after 5–10 s, it returned to the same opening at the base of the outcrop. On approach to 1.5 m from the opening, up to five newborn young were seen near the adult and although the adult did not advance again, it did rattle briefly. After a few minutes, one of the young crawled out of the refuge opening in front of the adult. The adult moved forward until it was resting on top of the young. The young struggled free and both returned to the opening. The posterior body and tail of the adult were notably thin, and the tail was proportionally short indicating a female. The young had a bluish cast and opaque pre-buttons, but the eyes were clear. The following day the adult and three or four young were present, but did not react to my presence. The next day there were two young and a shed skin with the adult, and on the fourth day neither the adult nor young were present. Later the opening under the overhang was found to extend horizontally at least 1.3 m.

Initially the refuge was approached directly with considerable commotion and twice the snake appeared to exhibit defensive behavior as I moved in its direction. This behavior was not observed on subsequent, stealthier visits. There are numerous accounts of pit vipers remaining with their young or eggs (Greene 1997. Snakes, the Evolution of Mystery in Nature. Univ. California Press, Berkeley, California. 288 pp.), but brood defense has only been reported for *Agkistrodon piscivorus conanti* (Walters and Card 1996. Herpetol. Rev. 27:203).

I thank Jillian Cowles, Harry Greene and David Hardy, Sr., for comments on the manuscript.

CROTALUS VIRIDIS LUTOSUS (Great Basin Rattlesnake). **MORTALITY.** Although rodents have been reported as enemies of rattlesnakes, especially in laboratory or enclosed situations (Klauber 1972. Rattlesnakes. Univ. California Press, Berkeley. 1536 pp.), documentation of interactions in nature is uncommon. Here, we 1) relate the mortality and possible predation of two *Crotalus viridis lutosus* to environmental temperature and condition of snakes at a natural hibernaculum, and 2) note the specific targeting of venom glands by a predator/scavenger. This observation was made at a large snake hibernaculum in Butte Co., Idaho, USA, on the property of the Idaho National Engineering and Environmental Laboratory.

FIG. 1. Body of *Crotalus viridis* showing extensive tissue loss. Note injury to the right venom gland and teeth marks on transmitter.

As part of a hibernation project on *C. v. lutosus*, we surgically implanted radiotransmitters (8–9 g) into seven adult female snakes and released them at their hibernaculum within one week. On 25 October 1991 we released the last two snakes: #349 (SVL = 77 cm, mass = 339 g) and #365 (SVL = 76 cm, mass = 321 g). On 4 November 1991, all seven radio-equipped snakes were underground within the hibernaculum and presumed alive. On 6 November, rattlesnakes #349 and #365 were found dead and mutilated at two different openings of the hibernaculum. Both snakes possessed injuries to the body; one had minor skin lacerations but the other suffered considerable tissue loss (Fig. 1). Most notable,

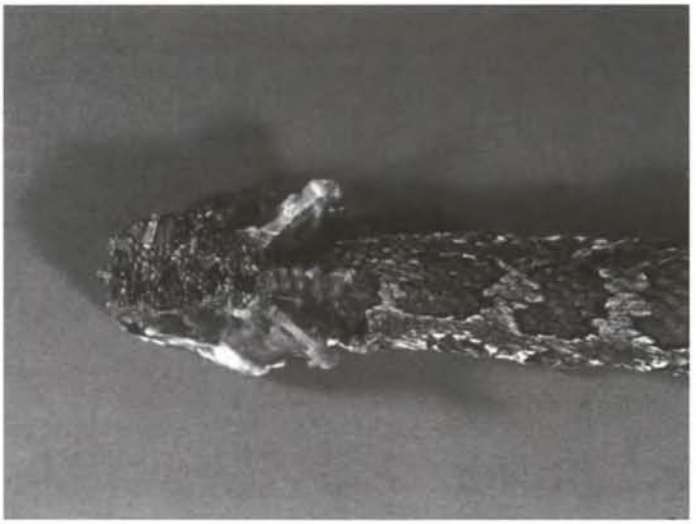

FIG. 2. Head of *Crotalus viridis* missing venom glands.

were the injuries to the lateral, posterior areas of the head, where the venom glands are located (Fig. 2). Both venom glands of one snake and one of the other were completely missing. Examination of the injuries and bite marks on one radiotransmitter suggested that the predator/scavenger was a rodent. The only likely rodent predator of rattlesnakes in this area is the bushy-tailed woodrat (*Neotoma cinerea*), a species commonly associated with this hibernaculum.

We suspect these two snakes were remaining active and basking near the entrances to the hibernaculum to promote healing of the suture site. Although we maintained the postsurgical snakes at warm temperatures for five days, healing may have been incomplete. Unfortunately, the weather worsened shortly after the snakes were released and remained relatively cool, allowing little time for the snakes to bask and maintain warm body temperatures. From release date until their death, operative snake body temperatures (measured with a datalogger and painted copper models) only rose above 20°C a total of 8.5 h. These reduced temperatures may have delayed healing and resulted in suboptimal locomotory and defensive performances (Peterson et al. 1993, *In* Seigel and Collins (eds.), Snakes: Ecology and Behavior, pp. 241–314. McGraw-Hill, New York), thereby increasing the snakes' vulnerability to predators. Halpin (1983. Am. Midl. Nat. 109:50–54) suggested that cool environmental temperatures may have facilitated a predation event on *Coluber* by prairie dogs (*Cynomys ludovicianus*), and Rowe and Owings (1990. Ethology 86:237–249) have suggested that ground squirrels can assess the risk of attacking a rattlesnake by detecting whether a snake is warm or not. Alternatively, the snakes may have died from other causes and been scavenged by rodents. Regardless of the mode of death, venom glands were specifically selected for consumption. We know of no other case where rodents have targeted snake venom glands. However, a possibly related observation involves wasps exhibiting specific attraction to the venom glands of freshly dead *C. viridis* on two separate occasions (Brent Charland, pers. comm.).

Submitted by **VINCENT A. COBB**, Department of Biology, Northeastern State University, Tahlequah, Oklahoma 74464, USA (e-mail: cobbva@cherokee.nsuok.edu); and **CHARLES R. PETERSON**, Department of Biological Sciences, Idaho State University, Pocatello, 83209, USA (e-mail: petechar@isu.edu).

ELAPHE FLAVIRUFA (Tropical Rat Snake). **PREDATION and DIET.** The only available record of the food habits of *Elaphe flavirufa* concerns the remains of an unidentified bird in the stomach of a snake collected in Mexico (Lee. 1996. The Amphibians and Reptiles of the Yucatán Peninsula. Cornell University Press, Ithaca, New York. 500 pp.). Here, we report a juvenile *E. flavirufa* feeding on two species of bats. On 20 July 1997 at ca. 2010 h, we observed a juvenile *E. flavirufa* (375 mm SVL; 472 mm total length; 22 g mass) on a wooden rafter (279 cm above the ground) in a thatched structure at the Lamanai Field Research Center, Indian Church Village, Orange Walk District, Belize. The snake was being attacked by two unidentified rodents, one of which seized the snake just behind the head and eventually killed it. A struggle then ensued between the two rodents over the dead snake, and shortly after the snake was dropped to the ground. The snake was collected, and subsequent examination of stomach contents revealed a black-winged little yellow bat (*Rhogeessa tumida*) and a little brown bat (*Myotis* spp.), both of which had been swallowed head-first. Frequently we observed bats roosting on the walls and ceiling of the thatched structure, and we suspect the bats in this instance may have been captured and eaten while roosting. The snake was deposited in the Campbell Museum (CUSC 1444), Clemson University, Clemson, South Carolina. The bats will be deposited in the American Museum of Natural History.

We are grateful to Bruce Miller for identifying the bats, Mark and Monique Howells for logistic support and accommodations at Lamanai Field Research Center/Lamanai Outpost Lodge, and Travis Crabtree for reviewing this manuscript.

LANGAHA MADAGASCARIENSIS (Leaf-nosed Snake). **REPRODUCTION**. On 10 September 1997, a wild collected, gravid *Langaha madagascariensis*was acquired by the Dallas Zoo's Department of Herpetology. On 2 October 1997, this specimen oviposited five eggs beneath a two-inch layer of sphagnum moss, which was used as a substrate in the specimen's enclosure. The eggs were measured (length [mean ± SD] = 24.4 ± 0.11 mm; width = 11.5 ± 0.08 mm). The eggs were incubated in a 1:1 mixture of vermiculite and water. Incubation temperature fluctuated from 24 to 27°C. Five neonates (125.6 ± 0.47 mm SVL; 1.5 ± 0.04 g) hatched after an incubation period of 81 days. Although human intrusion may have affected some of the data presented here, I believe this observation is noteworthy because nothing is known concerning the reproduction of this species in the wild.

My thanks to the staff of the Dallas Zoo Department of Herpetology for helpful comments and review of this manuscript.

Sumitted by **RICHARD D. REAMS**, Dallas Zoo Department of Herpetology, 650 R.L. Thornton Highway, Dallas, Texas 75203, USA.

LEPTODEIRA ANNULATA (False Mapanare, Banded Cat-Eyed Snake). **PREDATION**. Natural predation upon snakes by insects is rarely observed or photographically documented, and most reported cases involve mantid or water bug predators (Greene 1988. *In*: Gans and Huey (eds.), Biology of the Reptilia, Vol. 16, Ecology B. pp. 1–152. Alan R. Liss, New York); cases involving other insects are exceptional and occasionally remarkable (e.g., *Formica* ants; Graves 1989. Herpetol. Rev. 20:71). A group of students and one of us (ALM) observed predation upon a juvenile *Leptodeira annulata* (ca. 24 cm total length) by a carabid beetle (*Enceladus gigas* Bonelli, Tribe Siagonini; ca. 4 cm total length) at 2100 h on a blacktop road in northern Venezuela (Estado Guarico, 9 km ESE Paso Real) on 25 June 1997. The road traverses a xeric area with disturbed grassland and open bushy vegetational communities on gently rolling hills.

The snake had apparently just been captured when discovered as it was writhing rapidly and attempting to escape, and no exposed tissue or blood were evident at the site of the beetle's grasp, which was about 4 cm posterior to the snake's head. The snake did not attempt to bite the beetle. Within 1.5 min, the snake was immobilized, and its body was nearly severed at the point of attack, with lung tissue protruding from the incision (Fig. 1).

The freqency and significance of predation upon snakes by beetles are unknown. Larochelle (1990. The Food of Carabid Beetles [Coleoptera: Carabidae, including Cicindelinae], Fabreries, Suppl. 5, Association des Entmologistes Amateurs du

Quebec, Quebec. 132 pp.) compiled from the scientific literature a list of dietary items utilized by 1054 species of Carabidae, and snakes were absent. There is a detailed case of natural predation by a diving beetle larva (*Dytiscus*: Dytiscidae) upon a juvenile garter snake (*Thamnophis elegans*) reported by Drummond and Wolfe (1981, Coleopterists Bull. 35:121–124). This attack was similar to the one reported here in that both occurred near the snake's head, perhaps because it is a vulnerable area appropriate for a quick kill and/or to decrease the chance of being bitten by the snake.

FIG. 1. Juvenile *Leptodeira annulata* ca. 1.5 min. after capture by a carabid beetle (*Enceladus gigas*). The snake's body is almost completely severed at the site of the beetle's grasp.

Submitted by **ALLAN L. MARKEZICH**, Department of Natural Sciences and Engineering, Black Hawk College, Moline, Illinois 61265-5899, USA (e-mail: markezicha@bhc1.bhc.edu), and **PHILIP PARRILLO,** Insect Division, Field Museum of Natural History, Roosevelt Road at Lake Shore Drive, Chicago, Illinois 60605-2496, USA.

NERODIA ERYTHROGASTER (Plain-bellied Water Snake). **SIZE.** The record total lengths (SVL + tail length) for subspecies of *Nerodia erythrogaster* given in Conant and Collins (1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.) are 157.5 cm (*N. e. erythrogaster*), 149.9 cm (*N. e. flavigaster*), and 147.3 cm (*N. e. transversa*).

Here I report a female *N. e. flavigaster* (ALA 65-3860 in the Alabama Museum of Natural History) with a total length of 163.6 cm (131.9 cm SVL + 31.7 cm tail length). Approximately 1 cm of the tail is missing. The specimen is preserved in alcohol and was unable to be stretched in the manner of a live or freshly dead specimen. I captured this snake on the night of 16 April 1960, while it was swimming at Springhill Lake, Tuscaloosa Co., Alabama, USA. Accompanying me on the field trip were Gay M. Lake, Jr., Roy E. Smith, and William Gandrud. The specimen was preserved the following day by Shirley Whitt.

I thank Charles Lydeard (Curator of Herpetology, University of Alabama) for assistance in measuring the specimen. Michael E. Dorcas commented on the manuscript. Manuscript preparation was supported by Financial Assistance Award Number DE-FC09-96SR18546 from the U.S. Department of Energy to The University of Georgia Research Foundation.

Submitted by **J. WHITFIELD GIBBONS**, Savannah River Ecology Laboratory, Drawer E, Aiken, South Carolina 29802, USA.

NERODIA FLORIDANA (Florida Green Watersnake). **REPRODUCTION**. Large broods of *Nerodia floridana* are not uncommon, averaging 20–30 offspring (Tennant 1997. A Field Guide to Snakes of Florida. Gulf Publishing Co., Houston, Texas. 257 pp.), with a record litter size of 101 reported from Polk Co., Florida (Telford 1948. Herpetologica 4:184).

On 6 July 1997, a *N. floridana* was found in Orlando, Orange County, Florida, USA (28°32' 56"N, 81°19'08"W), on the edge of Lake Barton in a residential yard. The resident, mistaking the snake for an *Agkistrodon piscivorus* (Florida cottonmouth), killed it with a shovel. On 10 July 1997, the resident called one of us (FMM) to retrieve the snake, which had been kept in a cooler of ice. The snake was in good condition except for a small wound ca. 20 cm from the cloaca. After further investigation, the snake was found to have been gravid and four fully-developed snakes were removed from the wound.

The specimen was kept in a freezer and later transferred to the Florida Museum of Natural History on 8 August 1997. Subsequent examination revealed that the snake contained an additional 128 fully developed embryos, of which only one showed any external deformities (the ventral side of this snake was folded on itself and fused for the anterior two-thirds of its length). Pertinent data for 128 embryos is: length (mean ± SD = 257 ± 13 mm; range = 170–280 mm); SVL (192 ± 10 mm; 125–211 mm); and mass (10.0 ± 1.3 g; 2.4–11.7 g). The adult female measured 175.0 cm total length (135.0 cm SVL) only 13.0 cm short of the record total length for this species (Conant and Collins 1991. Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). Female mass without embryos was 2835 g. The total mass of the embryos (1274 g) represents 45% of the adult's mass (without embryos). The adult and 128 offspring were deposited in the collection of the Florida Museum of Natural History at the University of Florida (UF 109763). The identification was verified by R. Franz of the Florida Museum of Natural History.

To our knowledge, this is the largest litter size (132) recorded for any member of the family Colubridae and second only to a record litter for all snakes of 156 for *Bitis arietans* (Branch 1978. The Snake 9:67–86)

We thank Nick Wray and Mike Talbot for assistance measuring and preserving this large brood. We also thank Dick Franz, Jonathan Campbell, and Ron Gutberlet for assistance in preparing this note.

Submitted by **KENNETH P. WRAY**, Department of Biology, University of Texas at Arlington, Arlington, Texas 76019, USA, and **FLAVIO M. MORRISSIEY**, Curator of Zoological Services, 14501 South Orange Blossom Trail US 441, Gatorland, Orlando, Florida 32837, USA.

RHADINAEA BOGERTORUM (Oaxacan Graceful Brown Snake). **CLUTCH SIZE**. Despite extensive studies of reproduction in reptiles (Fitch 1970. Univ. Kansas Mus. Nat. Hist. Misc. Publ. 52:1–247) and a monograph of the genus *Rhadinaea* (Myers 1974. Bull. Amer. Nat. Hist. 153:1–256), no data exist on reproduction in *Rhadinaea bogertorum*. Two gravid females were found in the Comaltepec municipality, Oaxaca, México. The first specimen (SVL 330 mm, tail length [TL] 88 mm, mass 10.4 g) was found on 31 March 1988 by Efraín Hernández and deposited in

Museo de Zoología Facultad de Ciencias (MZFC 4518), and the second specimen (SVL 348 mm, TL 126 mm, mass 18.5 g) was collected by Leo Schibli on 8 October 1994 and deposited in Colección de Herpetología del Instituto de Biología (IBH 11280). The first female had 9 non-vitellogenic follicles (volume [mean ± SE (range)] = 2.59 ± 0.47 mm^3 [0.58–5.43 mm^3]) and 2 oviductal eggs; mass = 0.325 ± 0.0135 g [0.312–0.339 g]). Relative clutch mass (RCM) was 0.069 g. The second female had 12 non-vitellogenic follicles (volume = 3.85 ± 0.81 [0.627–8.34 mm^3]), and 7 vitellogenic follicles (volume = 74.1 ± 5.87 [50.9–93.7 mm^3]). These data support the idea that species of *Rhadinaea* have a relatively small clutch size (Fitch 1970, *op. cit.*).

Submitted by **AURELIO RAMÍREZ-BAUTISTA**, and **MARIO MANCILLA MORENO**, Departamento de Zoología, Instituto de Biología, UNAM, A.P. 70-153, C. U., C.P. 04510, México 20, Distrito Federal, México.

THAMNOPHIS ELEGANS VAGRANS (Wandering Garter Snake). **DIET**. The diet of *Thamnophis elegans* has been extensively studied in many portions of its range (Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman, Oklahoma. 332 pp., and references therein). On 31 July 1992 in the Jemez Mountains near Alamo Canyon, ca. 14 air km SW of Los Alamos (T18N R5E SE1/4 Sec. 9), Sandoval County, New Mexico, USA, CWP and MJA collected an adult *T. elegans* (279 mm SVL) that contained an adult Jemez Mountains salamander, *Plethodon neomexicanus* (ca. 59.8 mm SVL). The salamander was eaten tail first and the tail was completely digested up to the vent. These specimens are cataloged in the University of New Mexico Museum of Southwestern Biology as MSB 55407 (*T. elegans*) and MSB 55408 (*P. neomexicanus*).

On 20 July 1986 in the Sacramento Mountains, Water Canyon at the mouth of Telephone Canyon, ca 15.5 air km S of Cloudcroft (T17S R11E SE1/4 Sec. 24), Otero County, New Mexico, NJS and CWP collected an adult *T. elegans* (ca. 230 mm SVL) that contained an unidentified slug and a small Sacramento mountain salamander, *Aneides hardii* (30 mm SVL). The *T. elegans* is MSB 47339; the *A. hardii* was not cataloged. This is the first report of these New Mexico endemic plethodontid salamanders in the diet of *T. elegans*.

Submitted by **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, e-mail: cwpaint@unm.edu; **NORMAN J. SCOTT, Jr.**, U.S. Geological Survey, Piedras Blancas Research Station, P.O. Box 70, San Simeon, California 93452-0700, USA, e-mail: norman_scott@usgs.gov; and **MARILYN J. ALTENBACH**, New Mexico Natural Heritage Program, 851 University Blvd., Suite 101, Albuquerque, New Mexico 87131, USA; e-mail: altenbac@sevilleta.unm.edu.

UROTHECA (PLIOCERCUS) ELAPOIDES (False Coral Snake). **REPRODUCTION and DIEL ACTIVITY.** A female *Urotheca elapoides* (374 mm SVL) was collected on 12 January 1991 from Cuxta Bani, upper Raspaculo river, Maya Mountains, Belize, and deposited in The Natural History Museum, London (BMNH 1996.441). This snake was examined for signs of reproductive activity and found to contain five well-formed oviductal eggs. Egg sizes ranged from 18.5 x 6.5 mm to 21.5 x 8.0 mm, and averaged 20.2 x 7.5 mm.

Clutch size in this specimen falls within the range reported for *U. elapoides* (5–8 eggs) by Martin (1958. Misc. Publ. Mus. Zool. Univ. Michigan 101:1–102). The timing of reproduction, however, is unusual. Clutch deposition in specimens from Mexico (Greene 1969. J. Herpetol. 3:27–31; Martin, *op. cit.*) and El Salvador (Mertens 1952. Abh. Senckenb. Naturforsch. Ges. 487:1–120) has occurred during June–August, suggesting the summer wet season as the time of egg-laying in this species. The Belize snake was found gravid at the opposite time of year and, assuming that oviposition was imminent, the hatchlings would have almost certainly emerged during the local February–May dry season. This seems curious for a species that inhabits damp leaf litter and feeds largely on salamanders. Certain salamanders, however, may be reproductively active during the dry season; in neighboring El Petén, Guatemala, Duellman (1963. Univ. Kansas Mus. Nat. Hist. Publ. 15:205–249) found two species of salamanders (*Bolitoglossa doefleni* and *B. mulleri*) with eggs in February and March.

BMNH 1996.441 was found moving through wet leaf litter during the day (1530 h). Two other *U. elapoides* in Belize were observed foraging within a few m of each other on 26 May 1994 at 0800 h (vicinity of Ceibo Grande, Cayo District, pers. obs.), and there are two specimens from Toledo District in the Smithsonian collection (USNM 319776 and 319777; Union Camp, Columbia River Forest Reserve) also collected by day (5 and 7 April 1992). These observations concur with Smith and Chiszar's (1996. Species-Group Taxa of the False Coral Snake Genus *Pliocercus*. Ramus Publishing Inc., Pottsville, Pennsylvania. 112 pp.) assertion that *U. elapoides* is fundamentally diurnal in habits. Coincidental observations of the sympatric coral snakes *Micrurus diastema* and *M. hippocrepis* in Belize, which *Urotheca* appears to mimic, indicate that these species are also at least partly diurnal (pers. obs.).

The specimen was collected under authority of Ministry of Natural Resources (Belize) permits M/127/9/91(26) and 000159.

Submitted by **PETER J. STAFFORD**, Department of Botany, The Natural History Museum (BMNH), Cromwell Road, London SW7 5BD, UK.

GEOGRAPHIC DISTRIBUTION

Herpetological Review publishes brief notices of new geographic distribution records in order to make them available to the herpetological community in published form. Geographic distribution records are important to biologists in that they allow for a more precise determination of a species' range, and thereby permit a more significant interpretation of its biology.

These geographic distribution records will be accepted in a **standard format** only, and all authors *must* adhere to that format, as follows: SCIENTIFIC NAME, COMMON NAME (for the United States and Canada as it appears in Collins 1997. *Standard Common and Current Scientific Names for North American Amphibians and Reptiles*. Fourth Edition. SSAR Herpetol. Circ. 25:1–40; for México as it appears in Liner 1994, *Scientific and Common Names for the Amphibians and Reptiles of Mexico in English and Spanish.* Herp. Circ. 23:1–113), LOCALITY (use metric for distances and give precise locality data), DATE (day-month-year), COLLECTOR, VERIFIED BY (*cannot* be verified by an author—curator at an institutional collection is preferred), PLACE OF DEPOSITION (where applicable, use standardized collection designations as they appear in Leviton et al. 1985, *Standard Symbolic Codes for Institutional Resource Collections in Herpetology and Ichthyology,* Copeia 1985[3]:802–832) and CATALOG NUMBER (required), COMMENTS (brief), CITATIONS (brief), SUBMITTED BY (give name and address in full—spell out state names—no abbreviations).

Some further comments. This geographic distribution section does not publish "observation" records. Records submitted should be based on preserved specimens which have been placed in a university or museum collection (private collection depository records are discouraged; institutional collection records will receive precedence in case of conflict). A good quality color slide or photograph may substitute for a preserved specimen *only* when the live specimen could not be collected for the following reasons: it was a protected species, it was found in a protected area, or the logistics of preservation were prohibitive (such as large

turtles or crocodilians). Color slides and photographs *must* be deposited in a university or museum collection along with complete locality data, and the color slide catalog number(s) must be included in the same manner as a preserved record. Before you submit a manuscript to us, check Censky (1988, *Index to Geographic Distribution Records in Herpetological Review: 1967–1986*) to make sure you are not duplicating a previously published record.

Please submit any geographic distribution records in the **standard format only** to one of the Section Co-editors: Joseph T. Collins (USA & Canadian records only), Museum of Natural History—Dyche Hall, The University of Kansas, Lawrence, Kansas 66045–2454, USA; Jerry D. Johnson (México and Central America, including the Caribbean islands), Department of Biology, El Paso Community College, P.O. Box 20500, El Paso, Texas 79998-0500, USA; Hidetoshi Ota (all Old World records), Tropical Biosphere Research Center, University of the Ryukyus, 1 Senbaru, Nishihara-cho, Okinawa 903-01, Japan; or Gustavo J. Scrocchi (South American records), Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 Tucumán, Argentina. Short manuscripts are strongly discouraged, and are only acceptable when data cannot be presented adequately in the standard format. **Submissions by e-mail are encouraged where possible**. Refer to inside front cover for e-mail addresses of section editors.

Recommended citation for new distribution records appearing in this section is: Marques, O. A. V., and G. Puorto. 1996. Geographic Distribution. *Chironius laevicollis*. Herpetol. Rev. 27:212.

CAUDATA

AMBYSTOMA TIGRINUM (Eastern Tiger Salamander). USA: WISCONSIN: MARQUETTE CO: 3.2 km W Wisconsin Rt. 22 on Co. Rt. J, ca. 8 km N Montello, SW1/4 of NW1/4 Sec. 17, T16N, R10E. 17 October 1998. William S. Brooks. MPM 30316. Verified by Robert W. Henderson. New county record (Casper 1996, Geographic Distributions of the Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Mus. 1–87). Fills range gap ca. 15 km from nearest records mapped by Vogt (Vogt 1981, Natural History of Amphibians and Reptiles of Wisconsin. Publ. Milwaukee Public Mus. 205 pp.) and represents one of only seven localities for which records are available for Natural Division 4b, characterized by oak savanna, oak forest, and prairie; sandy loams; nearly level outwash plains and rolling moraine (Hole and Germain 1994, Natural Divisions of Wisconsin. Publ. Wisconsin Dept. Natural Res., Madison; Wisconsin Herp Atlas, Milwaukee Public Museum, unpubl. data). Lends credibility to only other reported observation in Marquette County by Lou Balaban from Sec. 11, T14N, R08E, in 1985 (Wisconsin Herp Atlas, *op. cit.*).

CAETÉ MUNICIPALITY: Lagoa do Cabral (20°00'S, 43°40'W, elev. 945 m). November 1991. L. B. Nascimento and R. N. Feio (MCN-AM 784–85). SÃO GONÇALO DO RIO ABAIXO MUNICIPALITY: Estação Proteção e Desenvolvimento Ambiental de Peti (19°49'S, 43°21'W, elev. 627 m). December 1989. L. B. Nascimento (MCN-AM 235). MARIANA MUNICIPALITY (20°22'S, 43°24'W, elev. 712 m). January 1993. R. N. Feio (MZUFV 913, 915, 917). These localities are in the trasition Atlantic Forest—Cerrado Domains. ARAÇUAÍ MUNICIPALITY (16°50'S, 42°04'W, elev. 307 m). May 1990. L. B. Nascimento and J. B. Isaac Jr. (MCN-AM 380). This locality is in the Caatinga Domain. All verified by U. Caramaschi and J. P. Pombal, Jr. Published distribution for the species is Atlantic forests from Bahia to the state of São Paulo, Brazil (Frost 1985, Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.) from sea level to an elev. of 800 m (Lutz 1973, Brazilian Species of *Hyla*. Univ. Texas Press. 260 pp.). First record for state of Minas Gerais.

Submitted by **LUCIANA BARRETO NASCIMENTO**, Departamento de Ciéncias Biológicas, Pontifícia Universidade Católica de Minas Gerais, 30.535-610 Belo Horizonte, Minas Gerais, Brazil, and **RENATO NEVES FEIO**, Museu de Zoologia João Moojen de Oliveira, Universidade Federal de Viçosa, 36.571-000 Viçosa, Minas Gerais, Brazil.

LITHODYTES LINEATUS (Sapito Lineado). VENEZUELA: ESTADO TÁCHIRA: Las Cuevas, Valle del Río Doradas, 550 m elev. J. Péfaur and R. Pérez. 14 February 1985. Colección de Vertebrados, Facultad de Ciencias, Universidad de los Andes, Mérida, Venezuela (CVULA IV-3652). Constitutes the only record in the country outside of the Guianan Shield in the states of Amazonas and Bolivar; more than 850 km to the NW of a nearer record in Venezuela, the High River Cunucunuma (Ginés 1959, Mem. Soc, Cien. Nat. La Salle 19[53]:85–146.). Lynch (1979. *In* W. E. Duellman (ed.). The South American Herpetofauna: Its Origin, Evolution and Dispersal, pp. 189–215. Mus. Nat. Hist. Univ. Kansas Monogr. No. 7.) showed a general distribution map for the species, where localities of the Andean piedmont are noted in Peru, Ecuador, and Colombia. First report for the Estado Táchira and for western Venezuela. Río Doradas valley constitutes the only place in the western region of the country with the presence of Amazonian elements.

Submitted by **CÉSAR LUIS BARRIO**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI, Apartado Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve).

ODONTOPHRYNUS AMERICANUS (Common Lesser Escuerzo). ARGENTINA: CORDOBA: Barreto (63°18'20"W, 33°20'43"S), Km 148, Ruta provincial N°4, 153 m. A. L. Martino. Laboratorio de Ecología, Facultad de Ciencias Exactas Físico-Químicas y Naturales, Universidad Nacional de Río Cuarto, Argentina (UNRC-ECO 609–612, 1 December 1998; UNRC-ECO 627–628, 15 October 1992; and UNRC-ECO 629–630, 15 October 1993). All verified by R. Martori. Males SVL 45–47 mm; females 35–36 mm. Males were calling in temporary pond; females were captured using pit traps.

Submitted by **ADOLFO L. MARTINO**, **NANCY E. SALAS**, and **ISMAEL E. DI TADA**, Ecología, Departamento de Ciencias Naturales, Facultad de Ciencias Exactas, Físico-Químicas y Naturales, Universidad Nacional de Río Cuarto, Km 601, Ruta Nacional N°36, (5800) Río Cuarto, Córdoba, Argentina (e-mail [ALM]: amartino@exa.unrc.edu.ar).

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog) USA: FLORIDA: VOLUSIA CO: New Smyrna Beach, Bouchelle Island on N side of S causway (Rt. A1A). 13 August 1996. UF 115254. Verified by Arthur C. Echternacht. New county record; extends the northern range of this non-native species on the E coast of Florida by ca. 120 km from a coastal Brevard County record (Meshaka 1996, Herpetol. Rev. 27:37–40), and ca. 40 km NE of four unpublished museum records from Seminole County near Sanford in 1993 (UF 87341–44; David Auth, pers. comm.). One male was collected from the crotch of a cabbage palm leaf (Sabal palmetto) on the E shore of the island. Three others (two males, one female) were observed in palms on the island, which is being developed as a residential community. During summer 1996 and 1997, isolated males were occasionally heard calling at night in and around New Smyrna Beach, a quaint coastal town with rapidly increasing residential and commercial development. As indicated by Meshaka (*op. cit.*), the use of imported palms and other landscaping plants from south Florida will likely result in the establishment of additional breeding populations in this county and additional north Florida counties.

Submitted by **TODD CAMPBELL**, Department of Ecology and Evolutionary Biology, 569 Dabney Hall, University of Ten-

nessee, Knoxville, Tennessee 37996, USA (e-mail: lizardman@utk.edu).

PSEUDACRIS CLARKII (Spotted Chorus Frog) USA: TEXAS: FREESTONE CO: Richland Creek Wildlife Management Area, North Unit, near Jct US Rt. 287 and FM 488. 16 March 1998. Toby J. Hibbitts. TCWC 80124. Verified by James R. Dixon. Specimen collected during biodiversity inventory conducted on the Richland Creek WMA. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **TOBY J. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA.

SYNAPTURANUS MIRANDARIBEIROI (Sapito Apuntado de Miranda Ribeiro). VENEZUELA: ESTADO BOLÍVAR. East slopes of Cerro Santa Rosa, Serranía del Supamo (06°37'N, 62°27'W). Jun 1990. F. Mendoza. Museo de Ciencias Naturales, Caracas, (MCNC 8080). Verified by O. Fuentes. First country record and the northernmost for the species. Reported by Nelson and Lescure (1975. Herpetologica 31:389–397) from some localities in Guyana, French Guyana, Surinam, and Brazil, and by Pyburn (1975. Herpetologica 31:439-443) from SE Colombia.

Submitted by **CÉSAR LUIS BARRIO**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI, Apto Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve) and **CHARLES BREWER-CARÍAS**, P.O. Box 90214 El Hatillo, 1083-A Caracas, Venezuela (e-mail: brewerch@ven.net).

SYRRHOPHUS CYSTIGNATHOIDES (Rio Grande Chirping Frog). USA: TEXAS: WALKER CO: Huntsville. 16, 19, 22 April 1998. New county record from three new localities; extends geographic range ca. 120.8 km N Houston (Harris County). Frogs were found in rocky refuges within small intermittent streams (Localities: 30°42'11"N, 95°31'59"W; 30°42'14"N, 95°33'1"W; and 30°42'53"N, 95°33'7"W). Sam Houston State Vertebrate Museum (SHSVM 0001-98, 0002-98, and 0003-98). Specimens verified by J. P. Caldwell, R. D. Durtsche, and L. J. Vitt.

Submitted by **WILLIAM I. LUTTERSCHMIDT** and **MONTE L. THIES**, Department of Biological Sciences, Sam Houston State University, Huntsville, Texas 77341, USA.

TESTUDINES

APALONE FEROX (Florida Softshell). USA: GEORGIA: LIBERTY CO: Fort Stewart Military Reservation: Fort Stewart Road 129, 3.2 km NW jct. with Georgia Rt. 119. 12 June 1998. Brian J. Platt, Mark Bradford. SOCM 1319 (photo). Verified by Robert A. Moulis. Adult found AOR crossing road near unnamed blackwater stream (tributary of Canoochee Creek). New county record (Williamson and Moulis 1994, Savannah Sci. Mus. Publ. 3:1–712).

Submitted by **DIRK J. STEVENSON** and **BRIAN J. PLATT**, Directorate of Public Works, Fort Stewart Fish and Wildlife Branch, 1557 Frank Cochran Drive, Fort Stewart, Georgia 31314, USA.

EMYDOIDEA BLANDINGII (Blanding's Turtle). USA: ILLINOIS: JASPER CO: Prairie Ridge State Natural Area. 187 m south of Co. Rd. 500N and 248 m west of Co. Rd. 1000E (NE 1/4, SW 1/4, Sec. 34, T6N, R9E). 4 May 1998. W. E. Louis. Illinois Natural History Survey (INHS photo vouchers 1998-10 and 1998-11). Verified by M. J. Dreslik. Recently added to the Illinois threatened species list; new county record, extending the historical Illinois range south (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. His. Surv. Bull. 298 pp.).

Submitted by **DANIEL J. OLSON** and **WADE E. LOUIS**, Department of Natural Resources and Environmental Sciences, University of Illinois, Urbana, Illinois 61801, USA.

GEOCHELONE CARBONARIA (Red-footed Tortoise). BRAZIL: PARÁ: Ilha do Marajó, Anajás (01°07'24.9"S, 49°34' 45.3" W). 22 January 1998. T. L. Pinto. Verified by U. Galatti. Museu Paraense Emílio Goeldi (MPEG 277). First record of this species on Marajó Island in the Amazonia region (Nascimento, Ávila Pires, Santos and Lima 1991, Bol. Mus. Para. Emílio Goeldi, sér. Zool. Belém 7:25–41; Pritchard and Trebbau 1984, The Turtles of Venezuela. Publ. SSAR, Miami University, Oxford, Ohio. 403 pp.).

Submitted by **GABRIEL SILVA PINTO**, Museu Paraense Emílio Goeldi, Departamento de Zoologia, Caixa Postal 399, Belém, Pará, Brazil, and **RUBENS NOBUO YUKI**, Faculdades Integradas do Tapajós, Rua Rosa Vermelha, 335, Aeroporto Velho, Santarém Pará, CEP: 68010-200, Brazil.

STERNOTHERUS ODORATUS (Common Musk Turtle). USA: ILLINOIS: JASPER CO: Prairie Ridge State Natural Area. 210 meters south of Co. Rd 500N and 274 meters west of Co. Rd. 1000E (NE 1/4, SW 1/4, Sec. 34, T6N, R9E). 18 May 1998. D. J. Olson. Illinois Natural History Survey (INHS Photo vouchers 1998-12 and 1998-13). Verified by M. J. Dreslik. New county record; fills in the expected distribution (Smith 1961, The Amphibians and Reptiles of Illinois. Illinois Nat. His. Surv. Bull. 298 pp.).

Submitted by **DANIEL J. OLSON**, Department of Natural Resources and Environmental Sciences, University of Illinois, Urbana, Illinois 61801, USA.

LACERTILIA

ANOLIS DISTICHUS (Bark Anole). USA: FLORIDA: BROWARD CO: Plantation. 11 July 1998. A. T. Reppas, K. L. Krysko, C. L. Sonberg, and R. H. Robins. Florida Museum of Natural History, University of Florida (UF 114327–329). Verified by F. Wayne King. New county record; indicates this non-indigenous species is expanding its range northward.

Submitted by **ANTHONY T. REPPAS**, Department of Interdisciplinary Studies and Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA, **KENNETH L. KRYSKO**, Department of Wildlife Ecology and Conservation and Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA (e-mail: kenneyk@flmnh.ufl.edu), **CARYN L. SONBERG**, Department of Education, University of Florida, Gainesville, Florida 32611, USA, and **R. H. ROBINS**, Florida Museum of Natural History, University of Florida, Gainesville, Florida 32611, USA (e-mail: rhrobins@flmnh.ufl.edu).

ELGARIA COERULEA (Northern Alligator Lizard). USA: NEVADA: DOUGLAS CO: Humboldt-Toiyabe National Forest, Spooner Summit, Rt. 50, unnamed National Forest Service road near a maintenance station, adult DOR with a broken tail (39°05'58"N, 119°54'25W), 2133 m elev. 12 November 1990. H. R. Panik. UNR 6949; Montreal Canyon, Humboldt-Toiyabe National Forest, ca. 0.4 km E on unnamed National Forest Service road, 1.3 km W jct. Rts. 28 and 50 (39°05'12"N, 119°54'12"W) 2152 m elev. Adult male found under a small cross-section of a pine log along a S-

facing slope in an aspen/pine forest. 12 August 1998. R. E. Espinoza, C. A. Carreño, A. R. Henderson, and R. W. Van Heest. UNR 6950. Both verified by J. Vindum. New county records; extends the range ca. 4.4 km SW (airline) from the closest reported locality at Clear Creek, Carson City (Vindum and Arnold 1997, Herpetol. Rev. 28:100). The database of the Nevada Natural Heritage Program also contains an unvouchered record for *E. coerulea* from a residential area in the city of Sparks (Washoe County, Nevada). Given the distance from other known populations in Nevada (e.g., 49.3 km NNE of Clear Creek), the lack of chief habitat requirements (Stebbins 1985, Peterson Field Guide to Western Reptiles and Amphibians. Houghton Mifflin, Boston, Massachusetts. 336 pp.), and the absence of records for this species from this densely populated area, we suspect the Sparks record is the result of a released or escaped individual rather than a naturally occurring population.

Submitted by **ROBERT E. ESPINOZA**, Biological Resources Research Center, and Ecology, Evolution and Conservation Biology, MS 314, University of Nevada, Reno, Reno, Nevada 89557, USA, **CARRIE A. CARREÑO**, Nevada Natural Heritage Program, 1550 East College Parkway, Suite 145, Carson City, Nevada 89706-7921, USA, and **RONALD W. VAN HEEST**, Biological Resources Research Center, University of Nevada, Reno, Reno, Nevada 89557, USA.

ENYALIOIDES HETEROLEPIS. PANAMÁ: PROVINCIA DE COCLÉ: Parque Nacional Omar Torrijos H., ca. 10 km N El Copé, headwaters of Río Guaybal, behind main park refugio on dirt road, ca. 600 m elev. 14 January 1998. Karen R. Lips. Fluid Vertebrate Collection, Southern Illinois University, SIUC R-3140 (photo). Verified by Robert Ibañez and Cesar Jaramillo. Adult male captured at night while sleeping on 1 m high stump along riverbank. Second capture was of juvenile sleeping ca. 1.5m over ground on sapling along trail ca. 100 m above same stream on 6 June 1998. New locality extends geographic range ca. 110 km west from Parque Nacional Soberanía, Panamá (Nicholson 1998, Herpetol. Rev. 29:174). New province record.

Submitted by **KAREN R. LIPS**, Department of Zoology, Southern Illinois University, Carbondale, Illinois, 62901-6501, USA.

EUMECES EGREGIUS SIMILIS (Northern Mole Skink). USA: GEORGIA: Candler Co: R. G. Daniels Preserve (The Nature Conservancy), ca. 5.8 km SE Metter. 8 March 1997. Dirk J. Stevenson and Beth A. Willis. SOCM 304. Verified by Robert A. Moulis. Adult found under debris in longleaf pine (*Pinus palustris*)/turkey oak (*Quercus laevis*)/wiregrass (*Aristida beyrichiana*) sandhill. New county record (Williamson and Moulis 1994, Savannah Sci. Mus. Publ. 3:1–712).

Submitted by **DIRK J. STEVENSON** and **BETH A. WILLIS**, Directorate of Public Works, Fort Stewart Fish and Wildlife Branch, 1557 Frank Cochran Drive, Fort Stewart, Georgia 31314, USA.

EUMECES GILBERTI RUBRICAUDATUS (Western Redtail Skink). USA: NEVADA: Nye Co: Nevada Test Site, Midway Valley on the E flank of Yucca Mountain, ca. 1130 m elev. (36°50'20"N; 116°26'15"W). 24 May 1995. C. L. Sowell and A. M. Ambos. BYU 46485. Verified by Jack W. Sites, Jr. Adult male (SVL = 79; TL = 120; 10.5 g); fills a distributional gap between Pahute Mesa (Medica et al. 1990, Herpetol. Rev. 21:40) and Grapevine Peak (Rogers and Fitch 1947, Univ. California Publ. Zool. 48:169–220). Specimen was collected in creosotebush (*Larrea tridentata*) bajada habitat which was drier and lower in elevation than would be expected for the species in this region (Banta 1962, Herpetologica 18:129–130). This was the only *E. gilberti* captured in this area during 6336 trap-days (24 h/d) of pitfall and funnel trapping and ca. 1000 person-days (4 h/d) of noosing conducted from 1991 to 1995.

Submitted by **JAMES L. BOONE** and **CHRIS L. SOWELL**, SAIC, 1261 Town Center Drive, Las Vegas, Nevada 89134, USA.

EUMECES TETRAGRAMMUS (Four-lined Skink). USA: ARIZONA: Cochise Co: Peloncillo Mountains, S Fork Skeleton Canyon, 1649 m elev. (31°31.41'N, 109°03.75'W). 9 August 1998. Andreas Noellert. Arizona State University (ASU 30936). Verified by Joseph T. Collins. First specimen from Arizona side of mountain range. (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.).

Submitted by **ANDY HOLYCROSS** and **BRIAN FEDORKO**, Biology Department, Arizona State University, Tempe, Arizona 85287-1501.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: FLORIDA: Levy Co: Cedar Key, concrete block wall of the public restroom at the City Park adjacent to the Cedar Cove Hotel, NW1/4 Sec. 32, T15S, R13E. 26 August 1997. Ryan C. Means and Guy H. Means. Florida Museum of Natural History, Gainesville, Florida (UF 112976). Verified by David Auth. Populations are known from Apalachicola in the Florida panhandle (Means 1996, Herpetol. Rev. 27:152) and Tampa in peninsular Florida (Nelson and Carey 1993, Northeast Gulf Sci. 13:53–58). New county record; helps close the gap in the Floridian Gulf Coastal distribution of this species.

Submitted by **RYAN C. MEANS**, Coastal Plains Institute and Land Conservancy, 1313 North Duval Street, Tallahassee, Florida 32303, USA.

LEPIDODACTYLUS LUGUBRIS (Mourning Gecko). MALDIVES: SOUTH MALE ATOLL: Vadoo (4°07'N, 73°27'E). 6 September 1998. Akira Kikukawa. Zoological Collection of Kyoto University (KUZ 47850). Verified by Hidetoshi Ota. First record for the Maldive Islands. Fills the distributional gap between India (Das 1996, Biogeography of the Reptiles of South Asia. Krieger Publ., Malabar, Florida) and the Chagos Archipelago (Barnett and Emms 1997, British Herpetol. Soc. Bull. 59:6–12). A few other individuals were also observed. Species appears to be rare compared to *Hemidactylus frenatus,* which is already known from the Maldives (Moutou 1985, C. R. Soc. Biogeogr. 61:101–109).

Submitted by **AKIRA KIKUKAWA**, Vadoo Diving Paradise, South Male Atoll, P.O. Box 20159, Republic of Maldives.

LEPOSOMA OSVALDOI. BRAZIL: AMAZONAS: Município de Borba, Santa Bárbara, left bank of Rio Canumó. 9 June 1994. M. S. Hoogmoed. MPEG 16965. Verified by Rubens Nobuo Yuki. First record for the state of Amazonas. Previously known only in the state of Rondónia (Ávila-Pires 1995, Lizards of Brazilian Amazonia [Reptilia: Squamata]. Zoologische Verhandelingen 299:1–706).

Submitted by **GABRIEL SILVA PINTO**, Museu Paraense Emílio Goeldi, Departamento de Zoologia—DZO, Caixa Postal 399, CEP 66040-170, Belém, Pará, Brazil.

PODARCIS ERHARDII (Erhard's Wall Lizard) EUROPE: GREECE: DODECANECE: Pergousa (36°35'E, 27°02'N) and Pachia (36°34'E, 27°04'N) islets west of Nisyros Island. 19 February 1993. Collected by the authors. Museum of Natural His-

tory, University of Crete, Greece, MNHUC E98–E103 (Pergousa) and MNHUC E118–E124 (Pachia). Verified by B. Chondropoulos. First observation of *Podarcis erhardii* east of Middle Aegean Gap. Nearby islands of Nisyros and Gyali, although in close proximity, are characterized by an eastern herpetofauna, where *P. erhardii* is replaced by *Ophisops elegans*.

Submitted by **EFSTRATIOS D. VALAKOS** and **PANAGIOTA MARAGOU**, University of Athens, Department of Biology, Section of Animal & Human Physiology, GR-15784 Panepistimioupolis, Athens, Greece, and **MOYSIS MYLONAS** University of Crete, Department of Biology, P.O. Box 1470, GR 711 10 Iraklio, Greece.

SERPENTES

ATRACTUS TORQUATUS. (Culebra Terrera Roja; Red Burrowing Snake). VENEZUELA: ESTADO BOLÍVAR: Cerro Santa Rosa, 100 km SSE El Manteco, 300 m elev. June 1994. F. García. Museo de Ciencias Naturales, Caracas (MCNC-8034). Verified by L. F. Navarrete. Species was reported for the first time in Venezuela by McDiarmid and Paolillo (1988. *In* Brewer-Carías 1988, Cerro de la Neblina, Resultados de la Expedición 1983–1987. FUDECI, Caracas) from the lower Baría River at the S edge of the country in the state of Amazonas, and noted that the specimen was to be housed in the American Museum of Natural History of New York (no catalogue number given). We report here the first vouchered specimen of this species deposited in a Venezuelan museum, constituting the first locality in the state of Bolivar and extending the distribution of this taxon in the country 800 km to the NE. The presence of this snake in Venezuela is not surprising, as it is distributed through all north Amazonian countries (Hoogmoed 1980, Zool. Verhan., Leiden 175:1–47; Martins and Oliveira 1993, Zool. Meded. Leiden 67[2]:21–40).

Submitted by **CÉSAR LUIS BARRIO**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI, Apartado Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve), **CHARLES BREWER-CARÍAS**, P.O. Box 90214, El Hatillo, 1083-A Caracas, Venezuela (e-mail: brewerch@ven.net), and **OSWALDO FUENTES**, Instituto de Medicina Tropical-Serpentarium. Apartado Postal 47423, Caracas 1041, Venezuela (e-mail: ofuentes@tyto.ciens.ucv.ve).

BOTHROPS MOOJENI (Brazilian Lancehead). PARAGUAY: DEPARTAMENTO CANINDEYU: Reserva Natural del Bosque de Mbaracayú, "Caseta Lagunita," 24°08'04"S, 55°25'38"W. 6 April 1995. E. Buongermini P., R. Palacios, and U. Svensson. Museo Nacional de Historia Natural del Paraguay (MNHNP 6831). Verified by Marta Motte. First confirmed record for the Oriental Region of Paraguay. One male collected in an abandoned house. Species was mentioned as of probable occurrence in eastern Paraguay based on a photograph (Campbell and Lamar 1989, The Venomous Reptiles of Latin America. Cornell Univ. Press, Ithaca, New York. 425 pp).

Submitted by **EMILIO BUONGERMINI P.**, Museo Nacional de Historia Natural del Paraguay, Sección de Herpetología, Caballero 1060, Asunción, Paraguay, CP 1324 (e-mail: subtropy@infonet.com.py) and **TOMAS WALLER**, Zavalía 2090 3°B, Buenos Aires, Argentina, CP 1428.

DENDROPHIDION DENDROPHIS. BRAZIL: ALAGOAS: Maceió (9°40'S, 35°43'W), Rio Largo (9°30'S, 35°50'W) and Muricí (9°14'S, 35°48'W) in small patches of Atlantic Forest. February 1993–September 1995. E. M. X. Freire. Museu de História Natural, Universidade Federal de Alagoas (MUFAL 327, 429, 1779, 2060, 2245). Verified by R. Fernandes. First record for the northeastern region of Brazil; extends range ca. 1500 km SE of Belém, Pará, Brazil (Cunha and Nascimento 1978, Publ. Avuls. Mus. Par. Emélio Goeldi 31:67–68).

Submitted by **ELIZA MARIA XAVIER FREIRE**, Departamento de Zoologia e Museu de História Natural, Universidade Federal de Alagoas, Rua Aristeu de Andrade, 452, Maceió, Alagoas, 57021-090, Brazil, and Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, 20940-040, Brazil.

ELAPHE GUTTATA (Corn Snake). USA: TEXAS: Lee Co: 6.4 km (by road) SW jct. Co. Rd. 123 and FM 141 on FM 141. 17 October 1998. John H. Malone. TCWC 81639. Verified by James R. Dixon. County record; fills distribution gap between Bastrop and Burleson counties. (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp; Dixon 1996, Ten year supplement to Texas herpetological county records published in Amphibians and Reptiles of Texas, 1987. Texas Herpetol. Soc. Spec. Publ. No. 2).

Submitted by **JOHN H. MALONE**, Herpetological Independent Study Group, Texas A&M University, Department of Wildlife and Fisheries Sciences, College Station, Texas 77843, USA, and **THAD J. WILLIAMS**, Texas A&M University, Department of Wildlife and Fisheries Sciences, College Station, Texas 77843, USA.

ERYTHROLAMPRUS PSEUDOCORALLUS. (Falsa Coral de Maracaibo, Maracaibo's False Coral Snake). VENEZUELA: ESTADO AMAZONAS: Gavilán, a small indigenous village 30 km ENE of Puerto Ayacucho. 3 January 1990. Collected by Piaroa Indians. Museo de Ciencias Naturales, Caracas (MCNC 7676). Verified by O. Álvarez. *Erythrolamprus pseudocorallus* had been recorded previously in the Maracaibo Basin in the states of Zulia and Merida, and was thought to be endemic to this region (Roze 1966, La Taxonomía y Zoogeografía de los Ofidios de Venezuela. Ediciones de la Biblioteca, Universidad Central de Venezuela Caracas. 360 pp.). First report of the species outside of the Maracaibo Basin, about 600 km to the SE; demonstrates a much wider distribution in the country and that the endemicity of the species is invalid for the Maracaibo Basin. Rodríguez-Acosta and Fuentes (1995–96 Terra 11–12[20–21]:77–84) mention the presence of this species in Amazonas, but without further explanation.

Submitted by **OSWALDO FUENTES,** Instituto de Medicina Tropical-Serpentarium, Apartado Postal 47423, Caracas 1041, Venezuela (e-mail: ofuentes@tyto.ciens.ucv.ve) and **CÉSAR LUIS BARRIO**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI. Apto Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve).

FARANCIA ABACURA REINWARDTII (Western Mud Snake). USA: TEXAS: Fort Bend Co: Brazos Bend State Park, 26.1 km (by air) ESE Rosenberg. 19 September 1998. John H. Malone. TCWC 81641. Verified by James R. Dixon. First live specimen documented from Fort Bend Co. (previous record was based on a fossil specimen; Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp; Dixon 1996, Ten year supplement to Texas herpetological county records published in Amphibians and Reptiles of Texas, 1987. Texas Herpetol. Soc. Spec. Publ. No. 2). Specimen collected under the authority of State Park Scientific Study Permit 60-98.

LIOPHIS MARYELLENAE. BRAZIL: BAHIA: Ibicoara (13°25'S, 41°17'W). 18 February 1989. Collected at nightfall while moving on the top of a "campo rupestre" (savanna of altitude rocky field). CZGB 568; Iramaia (13°18'S, 41°17'W). 21 February 1989. CZGB 570. Both collected by António J. S. Argôlo, Binael Santos, and Robson Nunes; both verified by Ronaldo Fernandes. These localities are situated between 600 m and 1040 m elevation; extends range over 500 km E from the unique previous record in the state of Bahia (Dixon 1985, Proc. Biol. Soc. Washington 98[2]:299.).

Submitted by **ANTÔNIO JORGE SUZART ARGÔLO**, Universidade Estadual de Santa Cruz—UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45650-000, Ilhéus, Bahia, Brazil, and Centro de Pesquisas do Cacau/CEPLAC, Km 22 Rodovia Ilhéus-Itabuna, CEP 45600-000, Ilhéus, Bahia, Brazil.

LIOPHIS POECILOGYRUS. VENEZUELA: ESTADO BOLÍVAR: El Palmar, 60 km E Upata. 1 February 1994. A. Hernández. Museo de Ciencias Naturales, Caracas (MCNC 8036). Verified by D. Briceño; Estación CVG Los Pijiguaos. February 1998. L. Andreani. (MCNC 7893). Verified by L. F. Navarrete. Sabanas de El Manteco, 20 km S El Manteco. March 1995. A. Hernández. (MCNC 8036). Verified by L. F. Navarrete. Dixon (1989 Smithsonian Herpetol. Infor. Serv. 79) pointed out the presence of this species in Venezuela. Dixon and Markezich (1992 Texas J. Sci. 44:131–166) clearly indicated the presence of this taxon in the state of Bolivar, Venezuela on their map (p. 136, two localities), but they did not mention vouchered specimens. We herein provide the first vouchers with precise localities in Venezuela.

Submitted by **OSWALDO FUENTES**, Instituto de Medicina Tropical-Serpentarium, Apartado Postal 47423, Caracas 1041, Venezuela (e-mail: ofuentes@tyto.ciens.ucv.ve) and **CÉSAR LUIS BARRIO**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI, Apartado Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve).

LIOPHIS SAGITTIFER MODESTUS. ARGENTINA: SANTA FE PROVINCE: Vera Department: Margarita (29°42'S; 60°13'W). 21 November 1972. A. Barrio. Herpetological collection of former Centro Nacional de Iología, now located in the Museo Argentino de Ciencias Naturales, Buenos Aires, Argentina (CENAI 3299, a male 268 mm SVL, 87 mm TL). Verified by G. Couturier. First record for Santa Fe province, extends range ca. 250 km air line E from nearest known population in Santiago del Estero province (Cei 1993, Mus. Reg. Sci. Nat. Torino Monogr. 14:609–610; Dixon 1989, Smithsonian Herpetol. Infor. Serv. 79:22–23; Dixon and Thomas 1982, Herpetologica 38:389–395).

Submitted by **VANESA ARZAMENDIA** and **ALEJANDRO R. GIRAUDO**, FAFODOC, Universidad Nacional del Litoral and Instituto Nacional de Limnología, INALI, CONICET, José Macia 1933, 3016 Santo Tomé, Santa Fe, Argentina

MASTICOPHIS BILINEATUS (Sonoran Whipsnake) USA: NEW MEXICO: CATRON CO: DOR, S side of Pleasanton on US Rt. 180 (33°17'03.1"N, 108°52'41.5"W). 4 August 1998. Toby J. Hibbitts and Terry L. Hibbitts. TCWC 80000. Verified by James R. Dixon. This record extends the range ca. 54 km ENE of Eagle Creek, Greenlee County, Arizona (CM 71184, 70746). Another record exists from the Gila River, Greenlee County, Arizona (CM 71425). This record may be closer to the specimen that we collected, but the data are not precise enough to determine the exact locality (Camper and Dixon 1994, Ann. Carnegie Mus. 63[1]:1–48.). In New Mexico, this species was previously known only from western Hidalgo County (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico, Univ. New Mexico Press, Albuquerque. xix + 431 pp.)

Submitted by **TOBY J. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA and **TERRY L. HIBBITTS,** 602 Hilltop Circle, Wylie, Texas 75098, USA.

OXYRHOPUS FORMOSUS. VENEZUELA: ESTADO BOLÍVAR: Javillal, Río Caura. 5 October 1993. Colected by Panare indians. Museo de Ciencias Naturales, Caracas (MCNC-8035). Verified by O. Fuentes. Species has a wide distribution in South America east of the Andes and north of 20°S latitude (Peters and Orejas-Miranda 1986, Catalogue of Neotropical Squamata. Part I. Snakes. Smithsonian Inst. Press, Washington). First citation of the species in Venezuela was by McDiarmid and Paolillo (1988. *In* Brewer Carías (ed.), Cerro de la Neblina, Resultados de la Expedición 1983–1987. FUDECI, Caracas) from Río Baría, Estado Amazonas. Our example was found 750 km NNE of the previous known locality and provides evidence that the distribution of *Oxyrhopus formosus* in Venezuela includes all lowlands of the Guianan Shield.

Submitted by **RENATO MATTEI** and **CÉSAR LUIS BARRIO**, Fundación para el Desarrollo de las Ciencias Físicas, Matemáticas y Naturales, FUDECI, Apartado Postal 185, Caracas 1010-A, Venezuela (e-mail: fudeci@reacciun.ve).

OXYRHOPUS GUIBEI (False Coral Snake). BRAZIL: ALAGOAS: Muricí (9°14'S, 35°48'W) and Rio Largo (9°30'S, 35°50'W) in small patches of Atlantic Forest. September–October 1995. E. M. X. Freire. Museu de História Natural, Universidade Federal de Alagoas (MUFAL 1390, 1561, 1825), and Museu Nacional, Universidade Federal do Rio de Janeiro (MNRJ 6724–25). Verified by U. Caramaschi. First record for the Northeastern Region of Brazil; extends range ca. 1000 km NE of Minas Gerais, Brazil (Zaher and Caramaschi 1992, Bull. Mus. natl. Hist. nat. 4, Sér. 14:805–827).

Submitted by **ELIZA MARIA XAVIER FREIRE**, Departamento de Zoologia e Museu de História Natural, Universidade Federal de Alagoas, Rua Aristeu de Andrade, 452, Maceió, Alagoas, 57021-090, Brazil, and Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, 20940-040, Brazil.

PHILODRYAS BARONI (Baron's Racer). ARGENTINA: SANTA FE PROVINCE: 9 de Julio Department: Pozo Borrado (28°56'S, 61°44'W). 19 February 1969. M. Mendoza. Herpetological collection of former Centro Nacional de Iología, now located in the Museo Argentino de Ciencias Naturales, Buenos Aires, Argentina (CENAI 2762, a female 1230 mm SVL). Verified by A. Giraudo. First record for Santa Fe province; extends range ca. 150 km airline E from nearest known population in Santiago del Estero province (Cei 1993, Mus. Reg. Sci. Nat. Torino Monogr. 14:632–635). Species previously known from Tucumán, Salta, Catamarca, Córdoba, Chaco, and Santiago del Estero provinces in Argentina (Cei 1993, *op. cit.*; Williams and Francini 1991, Boll. Mus. Reg. Sci. Nat. Torino 9:74).

Submitted by **VANESA ARZAMENDIA**, FAFODOC, Universidad Nacional del Litoral and Instituto Nacional de Limnología, INALI, CONICET, José Macia 1933, 3016 Santo Tomé, Santa Fe, Argentina.

PHILODRYAS LIVIDA. BRAZIL: GOIÁS: Municipality of Mineiros, Pargue Nacional das Emas (18°20'S, 53°00'W, 760–880 m elev.). 26 July 1997. M. B. Ramos Neto. (Instituto Butantan, São Paulo, Brazil, IB 57338). Verified by F. L. Franco. Species is known from 19 specimens from twelve localities in the states of São Paulo and Mato Grosso do Sul (Thomas and Fernandes 1996, Herpetologica 52:271–275). Formerly known as *Platyinion lividum* Amaral (1923); has been recently placed in the genus *Philodryas* Wagler (1830) by Thomas and Fernandes (1996, *op. cit.*). First state record; extends range about 150 km northward.

Submitted by **PAULA H. VALDUJO** and **CRISTIANO NOGUEIRA**, Seção de Herpetologia, Instituto Butantan. Avenida Vital Brasil, 1500, CEP 05503-900, São Paulo, São Paulo, Brazil and Departamento de Ecologia Geral, Instituto de Biociências, Universidade de São Paulo, Caixa Postal 11461, CEP 05422-970, São Paulo, São Paulo, Brazil.

SONORA SEMIANNULATA (Ground Snake). USA: ARIZONA: Coconino Co: Wupatki National Monument. 9 June 1951. Pierson. University of Arizona Herpetology Collection (UAZ 26371–72). Verified by George Bradley. First Arizona records north of the Mogollon Rim outside of the Inner Gorge of the Grand Canyon, and first record for the Little Colorado River basin. Extends range ca. 80 km SE of nearest records in Grand Canyon National Park, and ca. 115 km NNE of nearest populations in Yavapai County (Fowlie 1965, The Snakes of Arizona. McGraw Hill, New York. 164 pp.; Frost 1983, Cat. Am. Amphib. Rept. 333:1–4). This record suggests the species could be found almost anywhere in the southern Colorado Plateau region of NE Arizona, NW New Mexico, SE Utah, and SW Colorado.

Submitted by **TREVOR PERSONS**, U.S. Geological Survey, Forest and Rangeland Ecosystem Science Center, Colorado Plateau Field Station, Northern Arizona University, P.O. Box 5614, Flagstaff, Arizona, 86011-5614, USA.

TAENIOPHALLUS BREVIROSTRIS. BRAZIL: ACRE: PORTO WALTER: Igarapí São Luiz (8°50'17"S 72°54'23"W). D. Oren, F. S. Braga and D. Pimentel. 24 April 1996. Departamento de Zoologia, Museu Paraense Emílio Goeldi. MPEG 19031. Verified by Ulisses Galatti. First record for the state of Acre (Myers 1974, Bull. Am. Mus. Nat. Hist. 153[1]:1–262; Cunha and Nascimento 1978, Pub. Avulsas Mus. Goeldi 31:1–218; Cunha and Nascimento 1993, Bol. Mus. Para. Emílio Goeldi, Sér. Zool. 9[1]:1–191 [= *Rhadinaea brevirostris*]; Di-Bernardo 1992, Comun. Mus. Ciénc. Tecnol. PUCRS, sér. zool. 5[13]:225–256; Silva-Jr. 1993, Herpetol. Nat. Submitted by **RUBENS NOBUO YUKI**, Departamento de Zoologia, Museu Paraense Emílio Goeldi, CP 399, Cep: 66040-170, Belém, Pará, Brazil.

TANTLLITA LINTONI (Linton's Dwarf Short-tail Snake). NICARAGUA: JINOTEGA: Reserva Biosfera BOSAWAS, ca. 3 km S Ayapal at Río Curinwas, 200 m elev. (12°46.62'N, 85°23.17'W). 14 February 1998. G. Köhler. Forschungsinstitut und Naturmuseum Senckenberg (SMF 78606). Verified by L. D. Wilson. First record for Nicaragua; extends range ca. 250 airline km SE of record from mountains above Corozal, Departamento Atlántida, Honduras (Wilson and Meyer 1985, The Snakes of Honduras. 2nd Edition. Publ. Milwaukee Publ. Mus. 150 pp.).

Submitted by **GUNTHER KÖHLER**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a.M., Germany.

TROPIDODRYAS SERRA. BRAZIL: BAHIA: Santa Cruz Cabrália: Estação Ecológica do Pau Brasil (CEPLAC/ESPAB) (15°40'S 38°58'W) 0-100 m elev. 3 May 1995. Laurindo Xavier and António Cosme. Coleção Zoológica Gregório Bondar of the Centro de Pesquisas do Cacau (CZGB 3698). Verified by Ronaldo Fernandes. Specimen was found during the morning on the ground on the border of a primary forest. Species is found in northeastern, central, and southeastern Brazil (Amaral 1978, Serpentes do Brasil, Melhoramentos/ Universidade de São Paulo, 2 ed. São Paulo. 246 pp.). Two specimens already known from Bahia have

no specific locality (Thomas and Dixon 1977, Pearce-Sellards Ser. Texas Mem. Mus. 27:1–20). According to these authors, the specimen referred to *T. serra* by Günther (1861, Proc. Zool. Soc. London 12–18) may be *T. striaticeps*. This individual had been found in Ilhéus (14°47'S, 39°03'W), 0–50 m elev. However, despite twelve years collecting in this region, the species has never been found there (Argolo, pers. obs.). To the contrary, *T. striaticeps* occurs 160 km west, at localities that are at least 640 m above sea level (Argôlo, pers. obs.). These data suggest that the specimen reported by Günther (*op. cit.*) could in fact be *T. serra*. The record from Santa Cruz Cabrália confirms the occurrence of *T. serra* in the state of Bahia, where the species is, apparently, rare.

Submitted by **ANTÔNIO JORGE SUZART ARGÔLO**, Universidade Estadual de Santa Cruz—UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45650-000, Ilhéus, Bahia, Brazil, and Centro de Pesquisas do Cacau/CEPLAC, Km 22 Rodovia Ilhéus-Itabuna, CEP 45600-000, Ilhéus, Bahia, Brazil.

TROPIDODRYAS STRIATICEPS. BRAZIL: BAHIA: Barra do Choça (14°52'S, 40°39'W): Recanto da Adriana farm. 24 September–21 December 1997. J. O. Ruas. Coleção Zoológica Gregório Bondar of the Centro de Pesquisas do Cacau/CEPLAC (CZGB 6237–38); 1 January–28 February 1998. J. O. Ruas. CZGB 6508; 1 March–7 April 1998. J. O. Ruas. CZGB 6588, 6590; Juritî farm. 1 April–2 May 1988. P. A. Souza. CZGB 7077; 3 May–11 July 1998. P. A. Souza. CZGB 7440; Ribeirão do Largo (15°28'S, 40°45'W); Boa Sorte farm. 1 January–28 February 1998. Collector unknown. CZGB 6419; 1 April–3 May 1998. Collector unknown. CZGB 7082. All verified by Ronaldo Fernandes. All localities are situated between 640 and 860 m above sea level and harbour deciduous and semideciduous seasonal Atlantic rainforests as well as evergreen Atlantic rainforest. First records to the Brazilian northeast; extend range ca 500 km N from the previous known limit (Thomas and Dixon 1977, Pearce-Sellards Ser. Texas Mem. Mus. 27:1–20).

Submitted by **ANTÔNIO JORGE SUZART ARGÔLO**, Universidade Estadual de Santa Cruz—UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45650-000, Ilhéus, Bahia, Brazil, and Centro de Pesquisas do Cacau/CEPLAC, Km 22 Rodovia Ilhéus-Itabuna, CEP 45600-000, Ilhéus, Bahia, Brazil.

VIRGINIA VALERIAE (Smooth Earth Snake). USA: TEXAS: Nacogdoches Co: A decapitated *Virginia valeriae* and a *Coluber constrictor* were regurgitated by an adult *Micrurus* captured on Melwood Circle in Nacogdoches, Texas, on 10 October 1997. The specimen of *Virginia valeriae* is a new county record (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M Press, College Station. 434 pp.). J. Howard Williamson. TCWC 81519. Verified by James R. Dixon.

During the last ten years, several collections and studies of anurans in the Parque Estadual do Rio Doce (19°48' and 19°29'S, 42°38' and 42°28'W), in southeastern part of the state of Minas Gerais, Brazil, have been conducted by us, resulting in new records of distribution of some species. All of them are typical of the east coast of Brazil and are known only from this region (Frost 1985). The Parque Estadual do Rio Doce represents the first recordings of this species in Minas Gerais territory and the most inland registered in Brazil, amplifying significantly the distribution of these species. All records are based on specimens deposited in the herpetological collections of the Museu de Zoologia João Moojen de Oliveira (MZUFV) at Universidade Federal de Viçosa, Viçosa, Minas Gerais, and Museu Nacional, in Rio de Janeiro

(MNRJ). The identifications are verified by J. P. Pombal Jr. (Curator, MNRJ).

Aparasphenodon brunoi. Marliéria Municipality: Parque Estadual do Rio Doce, Porto Capim. 10 October 1992. R. N. Feio, L. G. Cotta and L. W. F. Assad. The European wall lizard, *Podarcis muralis*, is native to southern and central Europe and northwestern Asia Minor. Within its geographical range, the species frequents rock faces, sparse woodlands, and landscapes modified by human habitation. Hospitable urban habitats include debris piles of stones and brush, unmortared brick and fieldstone walls, and rock ballast and splintered wooden ties in railroad right-of-ways (Arnold and Burton 1978; Hedeen 1984; Street 1979).

Several thousand *Podarcis muralis* occupy these urban habitats within the metropolitan area of Cincinnati, Ohio, USA (Kwiat and Gist 1987; Brown et al. 1995). The animals are the descendants of two lizards that were deliberately introduced from Italy in 1951 (Hedeen 1984; Vigle 1977). The purpose of this note is to report on the dispersal of this population.

The range expansion of an introduced species is by two modes: diffusion and jump-dispersal (Pielou 1979). Diffusion is a population's gradual spread over a period of several generations. Jump-dispersal is the rapid movement of individual organisms over large distances, followed by the establishment of satellite populations at the destinations. The two modes have been combined during the range expansions of many introduced plant (Baker 1986), insect (Simberloff 1986), and fish (Ehrlich 1986) species.

Jump-dispersal of introduced *Podarcis muralis* occurred as humans captured lizards from the area of colonization and established satellite populations in Ohio (Hedeen 1988) and Kentucky (Draud and Ferner 1994). The major mode of spread, however, has been by diffusion from the release site of the two founding lizards in a backyard between Melville Lane and Torrence Court. The founders' descendants have dispersed in all directions into the surrounding area, causing the neighborhood to become known as Lizard Hill.

At a distance of 400 m south of the original release site, the spreading population reached a northern bend of an east-west railroad right-of-way. From this bend between Lewis Street and Waterloo Avenue, the population diffused at least 1.0 km west along the railroad tracks toward downtown Cincinnati. However, by 1997, the lizards' western limit along the tracks had shrunk to a point 200 m west of the bend. The factors causing this range shrinkage are unknown.

The population also spread along the railroad tracks east from the bend, reaching a distance of at least 5.6 km by 1977. At a junction 6.9 km east of the bend, the lizards encountered tracks running north that split from the tracks continuing east. By 1997, the growing population had spread from the junction 2.5 km along each set of tracks, reflecting a uniform rate of dispersal along each roadbed.

The lizards diffused from the right-of-way into adjacent residential and commercial districts. In 1997, the greatest known distance of lizards from the railroad tracks was 2.4 km. The population's diffusion through residential and commercial areas has been comparatively slow, since hospitable habitats are separated by inhospitable habitats such as streets, parking lots, lawns, and dense stands of trees. Population spread has been more rapid along the continuous hospitable terrain provided by the railway's rock ballast and wooden ties.

Railroad right-of-ways limit the range expansion of some animals (Hengeveld 1989), but serve as favorable habitat corridors that accelerate the dispersal of other animals (Johnson and Choromanski-Norris 1992) as well as plants (Foy et al. 1983). Railway routes have aided the dispersal of *Podarcis muralis* in the Cincinnati area.

New Missouri Amphibian and Reptile Distribution Records from a Catalogued College Teaching Collection

GEOFFREY R. SMITH
and
LINDA D. JOHNSON
Department of Biology, William Jewell College
500 College Hill, Liberty, Missouri 64068, USA
e-mail (GRS): smithg@william.jewell.edu

Although the distributions of many Missouri amphibians and reptiles are well known and well documented throughout the state, many other species have potentially widespread distributions throughout the state but are poorly documented, particularly around the edges of their expected distributions (see Johnson 1987; Powell and Daniel 1997). One region of relatively poor documentation includes the counties just north of the Missouri River (see maps in Johnson 1987; see also Powell and Daniel 1997). These counties often form the northern border of expected distributions of many species, perhaps because of the natural barrier of the Missouri River.

Here we document several new county records for amphibians and reptiles in Missouri, with many of these records coming from counties immediately north of the Missouri River. These records were obtained from the teaching collection of William Jewell College (WJCTC). All records confirmed by J. E. Rettig.

ANURA

Bufo woodhousii fowleri (Fowler's Toad). Camden Co: Sec. 29, T38N, R17W. 18 May 1962. I. Hirano. WJCTC 6302. New county record from a zone of potential intergradation between *B. woodhousii woodhousii* and *B. woodhousii fowleri* (see Johnson, 1987).

Hyla versicolor/chryscocelis Complex (Gray Treefrog). Clay Co: Liberty, Cemetary at William Jewell College, Sec. 8, T51N, R31W. 23 May 1967. C. Smith. WJCTC 1737. New county record for complex (i.e., neither *H. versicolor* nor *H. chryscocelis* have been documented in this county).

Rana areolata (Crawfish Frog). Jasper Co: on Hwy. 171. 5 May 1962. M. Armstrong. WJCTC 821. New county record, filling gap in distribution.

Rana blairi (Plains Leopard Frog). Clay Co: Liberty near bridge over Missouri River, Sec. 18, T54N, R30W. 5 May 1962. G. Newton. WJCTC 6184. New county record.

LACERTILIA

Cnemidophorus sexlineatus (Six-lined Racerunner). Clay Co: Shoal Creek at Wabash RR. 5 July 1950. L. J. Gier. WJCTC 1591. New county record at N edge of expected distribution in Missouri. Clinton Co: Hufft Farm, Sec. 17, T54N, R30W. 5 May 1962. G. Netwon. WJCTC 6196. New county record at extreme N edge of expected distribution in Missouri.

Eumeces fasciatus (Five-lined Skink). Morgan Co: Sec. 9, T40N R18W. 21 April 1962. A. Miller. WJCTC 6256. New county record, filling hole in Missouri distribution.

Scincella lateralis (Ground Skink). Clay Co: on mud bank along stream, Sec. 34, T52N, R31W. 13 May 1967. F. Johannsen. WJCTC 1729. New county record, extends documented range in Missouri NE by > 40 km.

SERPENTES

Carphophis amoenus vermis (Western Worm Snake). Clay Co: under rock in field, Sec. 34, T52N, R31W. 13 May 1967. F. Johannsen. WJCTC 1707. New county record, filling hole in Missouri distribution.

Heterodon platirhinos (Eastern Hognose Snake): Hickory Co: Pomme de Terre Lake, Sec. 35, T37N, R22W. 3 May 1964. A. Lewis. WJCTC 1228. New county record, filling hole in center of Missouri distribution.

Nerodia erythrogaster transversa (Blotched Water Snake). Clay Co: Cooley Lake, SE 1/2 SE 1/4 Sec 2 T51N R30W. 1968. J. Littleford. WJCTC 1839. New county record.

Nerodia rhombifer (Diamondback Water Snake). Clay Co: By old Missouri River channel, Sec. 28, T51N, R31W. 15 May 1965. J. Bean. WJCTC 1464. New county record.

Opheodrys aestivus (Rough Green Snake). Hickory Co: Pomme de Terre Lake, Sec. 35, T37N, R22W. 3 May 1964. M. Wood. WJCTC 1236. New county record, filling hole in Missouri distribution.

Thamnophis proximus (Western Ribbon Snake). Clay Co: Cooley Lake, Sec 2, T51N, R30W. 20 May 1967. G. Beets. WJCTC 1711. New county record.

Thamnophis radix radix (Eastern Plains Garter Snake). Clay Co: near old Missouri River Channel, Sec 28, T51N, R31W. 8 May 1965. J. Bean. WJCTC 1470. New county record.

Tropidoclonion lineatum (Lined Snake). Ray Co: Sec. 32, T53N, R29W. 29 April 1962. J. Eddington. WJCTC 6341. New county record.

In addition to the information provided on amphibian and reptile distributions, these records point out the value of small college teaching collections. Many small colleges have collections of vertebrates (and invertebrates) for use in the classroom or in laboratories which are often the result of the efforts of broadly trained natural historians who worked at these small colleges during the middle part of the 20th century. If records have been kept and specimens properly labeled and preserved, such collections may contain a wealth of distributional data, as well as historical information useful for assessing population persistence. These collections may also come from relatively uncollected areas. For example, the WJCTC increased the known county records for reptiles in Clay County by 35% (from 20 to 27). Thus we suggest herpetologists at small colleges examine their teaching collections for possible distribution records.

Acknowledgments.—This note is dedicated to all the excellent natural historians who have taught at small colleges over the years, and in particular C. Newlon of William Jewell College, and J. B. Cope and the late G. Ward of Earlham College, for their influence on one or both of us. J. Rettig made helpful comments on an earlier version of this manuscript.

BOOK REVIEWS

A Field Guide to Reptiles and Amphibians of Eastern and Central North America, by Roger Conant and Joseph T. Collins. 1998. Houghton Mifflin Company, Boston and New York. Peterson Field Guide Series. Third edition, expanded. xviii + 616 pp., 48 color plates, 101 color photographs, 333 maps. Softcover US $20.00. ISBN 0-395-90452-8.

ROBERT POWELL
Department of Natural Sciences, Avila College
Kansas City, Missouri 64145, USA
e-mail: powellr@mail.avila.edu

The Peterson Field Guides to North American amphibians and reptiles are modern classics responsible for introducing many individuals to herpetology. They remain the most useful tools a herpetologically inclined person can take into the field. High quality illustrations indicating diagnostic characters, accurate maps, and cogent descriptions render these volumes superior to their competitors. All of the relevant features, good and bad, of the third edition of the "eastern" guide were discussed in detailed reviews by Mitchell (1992) and Good (1992), and I am not inclined to repetition. However, the recent publication of an "expanded" third edition warrants comment.

Although the description of new species, new introductions into the region, nomenclatural changes, and reevaluations of the status of subspecies since the publication of the original third edition in 1991 might suggest a need for a fourth edition, neither the text nor the plates have been changed. Consequently, the content is nearly a decade out of date (the "western" guide by Robert Stebbins is even more critically in need of revision). What has been altered in this expanded edition is the appearance and size of the book. This has resulted primarily from incorporating over 100 color photographs of selected taxa (credited on pages 595–596) and, to a lesser extent, the reorganization of the volume. Whether these changes were warranted or necessary is largely a matter of taste, as both positives and negatives accrued as a result.

On the positive side of the ledger, the book is much more attractive. Because one of the major groups at which the volume is directed consists of "amateurs," who are most likely to be influenced by appearance, this may have been the major motivation for the expansion. Nevertheless, glossy paper throughout, extensive use of color (including headers, frontice pieces, and maps), and generally high quality (some quite exquisite) photographs will be appreciated by even the most jaded "professional." Also positive was the relocation of the maps from the back of the book to close proximity of the relevant text. Although this precludes an easy comparison of ranges facilitated by the older format, most users will appreciate not having to flip between text and maps.

On the downside, the book has grown to an extent to which it is no longer easily carried in the field, presumably where it is to be most frequently used. Because color photographs, admittedly attractive, are provided for only some taxa, they contribute considerably less to the diagnosis of animals than the plates, which are still grouped, albeit now in the front of the book. Also, the relocation of the maps has caused many of them to be downsized, often to a degree where detail is lost and, as a result, a loss of utility is experienced. Amphibians and reptiles, unlike birds and even mammals, are relatively sedentary, so accurate maps are possible and frequently important, as geographic origin is critical for the proper identification of many taxa (this will become even more of a factor with a fourth edition which will include even more cryptic forms not otherwise easily distinguishable).

Was this expansion necessary? No, except as a marketing device. Instead, the publisher invested considerable time and money, when only a little more would have truly improved the product. Not only could a fourth edition have incorporated the cosmetic changes made herein, the composition of the regional herpetofauna, the taxonomy, and the distributions would have been current. Some concerns raised by previous reviewers (e.g., treatment of subspecies, common names, and the missed opportunity to educate users regarding the dynamic nature of systematics at all levels by including a few citations and explanatory remarks) could have been addressed. The size issue might be avoided by producing separate volumes on amphibians and reptiles, allowing all taxa to be illustrated with photographs and maps to be larger. Also, the omission in some maps of extralimital regions (e.g., the West Indies and large portions of México) would allow those portions of the range in the United States to be enlarged and imbued with greater detail. In addition, with the use of glossy paper throughout, plates could be inserted individually near maps and text, enhancing the utility of the book immensely.

Should you run to the nearest bookstore and buy one? Maybe. Make the effort only if you don't have an intact copy of the 1991 publication. However, if your copy is falling apart or you never got around to buying one, and in spite of my critical remarks, you will not find at any price a more useful, accurate, and attractive volume for identifying amphibians and reptiles in the eastern and central United States and Canada.

e-mail: Ken_Dodd@usgs.gov

In his lifetime, Edward Drinker Cope sparked intensive debate involving both style and substance. He will always be remembered for his voluminous contributions to herpetology (Adler 1989), paleontology, ichthyology, and other scientific disciplines. Less known, and perhaps with good reason, are his views on women (he opposed suffrage and thought women incapable of directing their affairs without masculine guidance), questions of race (he was clearly a white supremacist), his neo-Lamarckian approach to evolution, and his financial failures. As the namesake of the journal *Copeia*, we are reminded of him every time we consult its pages. His ego was immense and self-serving, his energy and knowledge unbounded, his ability to carry a grudge legendary, and his devotion to his daughter unquestioned, despite a long separation from his wife. With such a complex, prolific, and important figure in late 19th Century science, it is surprising perhaps that more has not been written about him. Davidson's book, issued on the centennial of his death, both assists and falls short of helping bring his persona to light.

The book is composed of eight chapters. The first four chapters trace Cope's early life and professional development (Cope's Early Life, The 1860s, Field Research in the 1870s and 1880s,Wading in the Marshiana: the Cope-Marsh War). The second four chapters are meant to provide a personal glimpse of Cope and how he was perceived by his family, friends and colleagues (Cope's Life with his Wife and Daughter, Cope's Contemporaries on Cope, What Happened at the End, Cope on Human Evolution, Society, and Religion). The book contains three appendices tracing the Cope family genealogy, the Cope-Hayden correspondence, and a glossary of important persons in Cope's life. As interesting as the text may be, I often found the Notes, comprising 28 pages of small type text, to be far more engrossing. Much of this information should have been included in the main body of the text. One cannot read the text without often referring to the Notes.

Davidson clearly conducted an exhaustive amount of background research in delving into Cope's life. Much of this information is contained in the archives of the Academy of Natural Sciences and the American Museum of Natural History. She read so much of Cope's writing that she was able to discern differences in the pattern of his scrawl, to note that the handwriting became even more illegible the more excited or agitated he became. Interpretation is a difficult art, however, and although I found myself in agreement with many of her interpretations (such as the origin of the Cope-Marsh feud and Cope's manipulation of his father), other explanations are possible for some of his more erratic behavior and obsessions. For example, no matter how hard I tried, I could not accept Davidson's assertion of Cope's affair with 'Miss Collins' in South Dakota or some of the other women mentioned, at least based on the evidence presented. Cope seems to have been, by accounts, quite unfaithful to his wife, but with whom he dallied and when probably cannot be ascertained without much more solid information.

Davidson's stated objective was "to present Edward Cope as a real human being," and that she has done. Cope comes across as an individual so taken with his self-orchestrated role in life and superiority to those around him that one imagines he would have been quite insufferable (p. 143: "To put it in a simplistic manner, he did precisely what he wanted to do at all times during his life. The only consideration he gave the opinions which others might have had of his actions involved how those opinions might be used to further his aims, or conversely, impede his intentions"). Davidson offers sometimes insightful, if purely speculative, explanations for his behavior, as further on page 143 she discusses how his excessive self-obsession might have been interpreted by Cope as his birthright for being incredibly bright. On the other hand, his behavior may reflect a bipolar personality bordering on the paranoid schizophrenic—entertaining all the while, but not a person to be on the wrong side of.

In his early years, Cope seems to have mastered the art of telling others what they wanted to hear while expressing his true feelings between-the-lines. This trait served him well as he grew up (first in dealing with his father and later with his wife, especially concerning his Quaker beliefs), but with financial and professional independence, his outspoken character emerged to public view. Clearly, he was obsessed with paleontology and natural science, and nothing would have stopped him from pursuing his studies, not his father, farming, rivals, his financial disasters, Indian wars, or finally, his failing health. In some individuals, this forcefulness might have been termed passion, but passion seems too tame a word for the forces that drove Cope. That he died because, in part, he medicated himself (with formalin and belladonna) for a condition (a chronic urogenital problem, not syphilis as often whispered) that might have been treatable by surgery shows the intense level of his inflated self-reliance.

Cope, of course, was the 'Master Naturalist' which formed the basis for a flattering biography long after Cope's death (Osborn 1931). Although written from an obviously admiring point-of-view, *Cope: Master Naturalist* is a fascinating book because it reproduces so many of Cope's direct words (although sometimes carefully edited, as Davidson notes), something we miss in Davidson's work to a large degree. Davidson prefers to let others judge Cope's scientific contributions, and even treads rather lightly on the Cope-Marsh feud. Cope was an extremely nasty character on the attack, and often played fast and loose with the facts. The hysteria and orchestration of the charges against Marsh (a complex and egocentric character in his own right) and John Wesley Powell accentuate a view of Cope as paranoid. Although Davidson does not reproduce or footnote the dramatic January 1890 *New York Herald* headlines attacking Marsh and the U.S. Geological Survey, they add considerable weight to an unflattering view of Cope and his agenda. One wonders after reading the actual correspondence and headlines how Cope could have been taken seriously. But then, such attacks had little to do with science by the time they got into the hands of know-nothing anti-science Congressmen from Alabama and the West (Stegner 1954). In this respect, Cope's legacy on Congressional support for scientific inquiry had long lasting and dramatically detrimental effects, quite the opposite of what he might have liked.

The last few chapters of Davidson's important biography deal with Cope's relationship with others, especially his wife, daughter, other women, and his views on society. Davidson reveals that Cope and his wife had a strained relationship, especially in the end when she left him (something overlooked in other Cope biographies I have read). He clearly loved his daughter, and strove for her to have a rigorous education, something unusual for his

time, while at the same time advocating an inferior role for women in society. Cope was a ladies man, and despite the pious letters reprinted by Osborn (1931), apparently had no qualms about breaking his conventional marriage bonds. His views on blacks were strong and racist, even for his time, and although he probably objected, his views were used by racists of his day in their drive to assert scientific support for rather outrageous assertions of the biological inferiority of Africans and those of other cultures. And speaking of outrageous, the various terms he coined to cloak his neo-Lamarkian views on evolution (e.g., bathmogenesis, ergogenesis, mnemogenesis; see Osborn 1931) would do a present day cladist proud. Davidson delves into each of these topics in great detail. Reading these chapters can throw a rather wet rag on Cope's shining personality to those of us who grew up with his image as "Master Naturalist." I enjoyed Davidson's debunking of the syphilis myth, but wonder why she didn't ask a specialist whether Cope died from the drugs or the unnamed urogenital condition. One more paragraph could have been enlightening.

Although I greatly enjoyed reading Davidson's account and comparing her version of events and interpretation with other accounts, the book is not without flaws. Some of the chapters would have been better with more information presented in the text instead of the Notes. The end of the book is abrupt. It is as if Chapter 8 ended, and the final two paragraphs were added as an after-thought to close it out. Surely, a more complete ending or summary could have been written. I certainly disagree with Davidson's portrayal of Cope's brushes with Powell and the Geological Survey as of minor importance. Quite the contrary, his attacks had long-lasting effects, very carefully discussed by Stegner (1954), a source curiously overlooked by Davidson. Powell (and rational science in the West) was not a casualty of standing too close to Marsh, but a direct target of Cope's vendetta. I was surprised at Davidson's fascination with a postcard from "a Professor K. Mitsukuri, who was evidently (sic) a biologist or even a paleontologist from Tokyo Imperial University..." In fact, Professor Mitsukuri was a well-known developmental biologist who published important papers on the early development of the eggs of turtles. It does not seem surprising that he would contact Cope concerning papers on the phylogeny of vertebrates. And finally, Davidson washes over more recent developments in the saga of Professor Cope, such as his wild west tour in 1892 and his designation as type specimen for *Homo sapiens* (see Psihoyos and Knoebber 1994). However, she points out the lack of credible evidence to Psihoyos and Knoebber's (1994) assertion that Cope's skeleton showed signs of syphilis.

Finally, the book suffers from the lack of an index and the great number of grammatical errors or omissions. It is very difficult to locate topics or information in the text and notes without an index. There simply is no excuse for the large number of textual errors, which detract considerably from its readability. My copy is filled with circles where I found missing words or phrases, or where the text just doesn't make sense. The book could have used some proper editing. If a book is sloppy in editing, is the scholarship equally sloppy? I certainly hope not, as this book long will be cited as an authoritative work on Professor Cope.

Ultimately, *The Bone Sharp* is not the definitive biography of Edward Drinker Cope. Its interpretations need to be read in conjunction with his own words (see Osborn 1931, for instance) and with other biographies and historical treatises (e.g., Stegner 1954; Plate 1964; references provided by Davidson). Only then can the real complexity of E. D. Cope, the man, be understood separately from the scientist. Cope made important and long lasting contributions to natural science, but the man himself was difficult, contradictory, and often arrogant. As Davidson states, "He was a man enviable for his wealth, charm, intelligence and good looks, but he was a man one could not always understand or respect." *The Bone Sharp* presents a remarkable insight into Cope's personality and, although I am sure it will be much debated among science scholars, it is an important contribution. I highly recommend it.

INDRANEIL DAS

Institute of Biodiversity and Environmental Conservation
Universiti Malaysia Sarawak
94300 Kota Samarahan, Sarawak, East Malaysia
e-mail: idas@mailhost.unimas.my

Thirteen years ago, the Zoological Survey of India (hereafter, ZSI) published, as part of its *Handbook* series, a work on the Indian Testudines, authored by Binoy Krishna Tikader (formerly Director, ZSI, now deceased) and Ramesh Chandra Sharma (formerly Officer-in-Charge, Desert Regional Station, ZSI at Jodhpur, now retired). The work of Tikader and Sharma (1985), at present out of print, contained serious errors of omission and commission. Now, the ZSI has thought fit to ask the second author to revise the *Fauna of (British) India* series on reptiles.

The introductory chapters of the first of the three volumes, covering Testudines and Crocodylia, are an indication of what is to come. It contains, in poor grammar, a general introduction, sections on progress in herpetology in India and "adjoining countries," phylogeny (which contains some vague remarks on "stem reptiles" as well as the origin of turtles, which the author firmly states "emerged from the early cotylosaurs"), distribution, and zoogeography (too long-winded for this reviewer), affinities of the reptiles of India, characteristics of Class Reptilia (generally agreed to be polyphyletic), leading to the definitions of the Order Testudines and accounts of each of the families that occur in the region.

Each species account comprises a suggested English name, the scientific name considered valid by the author, a synonymy (copied from Smith 1931, errors and all), a description written in an nonscientific style (e.g., "This is a gigantic, flat, soft-shelled species..."; p. 130), distribution (mostly from Smith 1931), habits and habitat, and conservation status. The last two categories contain most (unintentionally) amusing notes that more often than not hark back to Victorian times.

Although the author notes that knowledge on the fauna has increased substantially since the last treatment by Smith (1931), the present work omits many important papers and books published in the post-Independence period, including those on turtle and crocodile distribution and natural history. The fact that the author himself has published not a single paper on the subject is a pointer, and most of the references appear to have been derived from the earlier *Handbook*, which, in turn, were culled from Pritchard (1979) and Groombridge and Wright (1982), for the references from the last 30 years. Consequently, there are no references from the mid-1980s onwards.

Like Smith (1931), this work covers the entire mainland of southeastern Asia, besides the Indian Subcontinent, despite the fact that the author has no field experience outside of India. Much of the text has been copied, sometimes verbatim, from existing works, and when it is original, frequently introduces new errors. For instance, on p. 80, Sharma misinforms us of the distribution of *Melanochelys tricarinata*, indicating that it is found only in Bihar, Bengal, and Assam. Studies in the last 10 years have shown that the range of this species is about twice as large. Likewise, for perhaps India's rarest turtle, *Kachuga sylhetensis* (pp. 100–101), the distribution as known today is larger than "Garo, Khasi and Naga Hills." On the other hand, some species, such as *Aspideretes leithii* (pp. 137–138) have been stated to have larger ranges than recognized by reliable authorities. More seriously, several turtle species are shown as absent from India, including *Cuora amboinensis, Morenia petersi*, and *Pelochelys cantorii* (listed as *P. bibroni*; see Webb 1995 for the valid name of the taxon from the region), all known to occur in the country (see for instance, Das 1991; 1995). The common English names are not those suggested in Iverson (1992), but rather have been manufactured by the author, with disastrous results: Travancore vegetable-eating turtle for *Melanochelys trijuga coronata* (these turtles are omnivorous); Garo and Khasi Hills tortoise for *Cyclemys dentata* (Asian leaf turtle is more commonly used for this widespread turtle); and Assam freshwater tortoise for *Pyxidea mouhotii* (the keeled box turtle, which is terrestrial).

Readers are spared the poor quality color and black-and-white plates of preserved and misidentified species that characterized the *Handbook*, although most of the line art has been taken from that work. Of the new additions, some of the oddest depict crocodilians with scale markers in mm!

Taxonomic decisions are either poor or the author had no recent literature at hand on the nomenclature of the turtles of the world (see for instance, Iverson 1992). Thus, he refers all Indian testudinids to *Geochelone* (contra Crumly 1984; 1985) all trionychines to *Trionyx* (inspite of the convincing results from the phylogenetic analysis of Meylan 1987), and the batagurids to Emydidae (contrary to Hirayama 1984 and Gaffney and Meylan 1988). The subspecies concept of *Lissemys punctata*, as given in Smith (1931) is followed, despite the findings of Webb (1980; 1982) on the occupancy of names in these turtles, and the "Travancore tortoise" is noted as *travancorica* (rather than *forstenii*, as suggested by Hoogmoed and Crumly 1984). The important works of Moll (1986, 1987) on the taxonomy of the genus *Kachuga* are also ignored, as is new information on the biology and morphology of *Aspideretes nigricans*, reported by Ahsan and Haque (1991) and Ahsan and Saeed (1989). Indeed, the systematic and distributional information on Indian turtles are considerably more refined than during the time of M. A. Smith, thanks to the research of Bhupathy (1994, 1995), Bhupathy and Choudhury (1994, 1995), Frazier (1986, 1992), Frazier and Das (1994), Groombridge et al. (1983), Moll (1986, 1987), Moll et al. (1986), Moll and Vijaya (1986), Vijaya (1982, 1983), and many other workers, although this is not evident from this volume. For the Indian crocodiles, several Ph.D. theses have explored questions on ecology, although only the more popular articles are listed. The dangers of using the present work for formulating conservation plans are obvious.

The glossary provides some entertainment for those with time: "juxtaposed—placed in opposition to not imbricate"; "beak—the horny covering of the jaws assuming the shape of bird's beak"; "kinesis—fee movement between the bones or bony structure"; and finally, my favorite, "ossicle—a little bone." Many names of geographical localities are dated—Celebes, Foochow, Burma, Hainan, USSR—to give a few examples.

There are numerous false and misleading statements, including "the flesh [of *Amyda cartilaginea*] is not considered much suitable for human consumption" (p. 141), reference to *Aspideretes hurum* as endangered (p. 139), hatchling predation of *Crocodylus palustris* by herons and storks as a cause for their endangerment (p. 152), and so on. In general, the poor grammar and editing makes it difficult to distinguish typographical errors from other awkward phrases and expressions. An obvious one, of course, is Crocodylia, which has been misspelled Crocodilia even on the first page of the book. The spelling of this Order has clearly troubled the author, as the incorrect version appears not only at the start of the section on crocodilians (p. 141), but also as a running head throughout (p. 141 et seq.). Most annoying is the fact that several species names are consistently misspelled, according to the ICZN Code: *Hardella thurgi* for *Hardella thurjii* (p. 92), *Kachuga smithi* for *Kachuga smithii* (p. 95), and *Testudo horsfieldi* for *Testudo horsfieldii* (pp. 122–123). Interestingly, the titles on the dust jacket and spine are slightly different *(Fauna of India. Reptilia. Testudines and Crocodilians. Volume: I).*

In summary, this is neither a popular work nor a technical synopsis of the subject. It does not provide accurate information, nor is it aesthetically pleasing (no color photographs, an ancient font type, printing sometimes showing through on the opposite page, every scute of every turtle illustrated bears a name tag!). It has an incomplete bibliography, which would falsely suggest to the ininitiated that not much is known about the southern (and because of the coverage of this work, southeast) Asian turtle fauna. The Foreword by the Director, ZSI (p. iii) makes it abundantly clear that works like these will continue to be used for "formulating proper conservation strategies for ... protection," which confirms our worst fears.

The information presented has evidently been gleaned almost exclusively from three sources: Smith (1931), Pritchard (1979), and Groombridge and Wright (1983). Thus, if you have these works, you will save shelf space by not purchasing the latest work of Sharma. One now awaits with considerable trepidation the companion volumes on lizards and snakes in the *Fauna of India* series.

Ladies in the Laboratory? American and British Women in Science, 1800–1900, by Mary R. S. Creese. 1998. 452 pp, illustrated; cloth; ISBN 0-8108-3287-9. Scarecrow Press, Inc., US $98.00.

GEORGE R. PISANI

Biological Sciences, University of Kansas, Lawrence, Kansas 66045, USA
e-mail: gpisani@falcon.cc.ukans.edu

The publisher's announcement of this exceptionally thorough reference states that it is "a systematic survey and comparison of the work of 19th-century American and British women in scientific research"; it also remarks "this well-organized blend of individual life stories and quantitative information presents [a] broad and methodical coverage on a hitherto unprecedented scale." The publisher's hyperbole is quite accurate! Mary Creese has written over 20 articles on women scientists since 1990; this is her most ambitious undertaking. Her spouse Tom collaborated on some of her other works, and on this book. It includes a 58-page bibliography of the works published in journals by the scientists chronicled; these were gleaned from *Catalogue of Scientific Papers, 1800–1900* (The Royal Society, London).

The book outlines the work of 680 women scientists grouped in the major categories of Life Sciences (7 chapters), Math and Physical Sciences (5 chapters), and Social Sciences (4 chapters); the chapters represent topical subdivisions of these major categories. The number of women featured is especially noteworthy as the time period selected was one of intensely rigid views of the societal roles women were expected to play; science was not eminent among these. This statement is not at all intended to suggest that this situation materially improved over the succeeding 75 years, but most certainly those women profiled in this thorough work must be considered pioneers in the process of challenging role-barriers. Creese in fact remarks (pp. ix, xi) that "...by far the greater number [of these scientists] were active during the last two decades of the century, the time when the first of the university-trained women (in many respects a most remarkable group) were beginning their careers." Certainly this trend applies to those in herpetology.

The balance between dry, factual accounting and interesting reading in a work of this sort is difficult to maintain; indeed, the author acknowledges her goal to position the book between biobibliographies (more narrowly focussed on particular disciplines or persons) and broad historical surveys (which usually fail to pay sufficiently close attention to how the subjects came to enter particular fields, and what they accomplished). The resultant text contains pleasant diversions from its encyclopedic cataloguing to explore the personal lives, motivations, mentoring and personalities of many of the scientists listed.

Given the rigid views of the day, I found it interesting that several of the scientists profiled in the section "Museum Taxonomists to Morphologists and Embryologists" were afforded early recognition and assistance in their chosen fields by some eminent contemporary male scientists like Spencer F. Baird (USNM) and David Starr Jordan (University of Indiana). Bolstered by Jordan's encouragement and research support, Rosa Smith became the first woman to join the San Diego Society of Natural History, and in

1887 was appointed jointly (with H. F. Lorquin) Curator of Fishes and Reptiles at the California Academy of Sciences. Also in that section we find:

- Mary Bowers (Wellesley College), who conducted meticulous and extensive neuroanatomical studies of *Eurycea bislineata* (then *Spelerpes bislineatus*), and histological studies of *Bufo terrestris* (then *B. lentiginosus*).
- Anne Bowers and Inez Whipple Wilder (Smith College)—respiratory anatomy of *Desmognathus*.
- Gertrude Crotty (University of Kansas and Radcliffe College)—turtle embryology.
- Julia Platt (whose relatively brief but noteworthy career spanned several institutions—a story worth reading in itself!)—amphibian (especially *Necturus*) osteogenesis.
- Catherine Hopley (Gardens of the Zoological Society of London)—anatomical and popular works on snakes, reptiles in general, and amphibians, as well as a number of short entomological studies.
- Lilian Sheldon and Alice Johnson (Bathurst College)—amphibian embryology.

This is not a book one sits down and reads like a novel or biography. It is a reference work, and will be most useful (indeed indispensible) to persons interested in the history of science and women's studies. Additionally, it will be an essential reference for herpetologists offering courses and seminars concerning Women in Science. Though costly, the excellent workmanship evident in its production, its level of scholarship, and the numerous charts comparing the distributions of authors and papers within fields and between countries return a wealth of information for the expense.

PUBLICATIONS RECEIVED

Sounds of North American Frogs, the Biological Significance of Voice in Frogs [Compact Disc], by Charles M. Bogert. 1998. Smithsonian Folkways Recordings, 955 L'Enfant Plaza, SW, Suite 7300, MRC 953, Washington, D.C. 20560, USA. Compact Disc + 40 pp. accompanying booklet. US $14.00.

This is a reissue of Bogert's classic 1958 series of frog recordings. Fifty-seven taxa are represented in the 92 tracks, featuring anurans from across North America. In addition to updated track notes, the associated booklet contains the text of the essay "The Biological Significance of Voice in Frogs," written by Bogert at the time of the original release, as well as a new introduction by Richard G. Zweifel, and biographical sketch of the late Charles M. Bogert. Bogert himself narrated the tracks, which present a variety of advertisement calls, as well as other vocalizations. This reissue makes this pioneering work available on CD for the first time and will serve to remind herpetologists, especially those too young to remember the original release of the album, of the historical significance of Bogert's work in the field of animal sound study.

Monitoring Vertebrate Populations, by William L. Thompson, Gary C. White, and Charles Gowan. 1998. Academic Press, Inc., 525 B Street, Suite 1900, San Diego, California 92101-4495, USA. xv + 365 pp. Hardcover. US $64.95. ISBN 0-12-688960-0.

This book is designed as a guide for biologists and managers who require information about survey design for the purposes of estimating population size. As such it will prove valuable to those involved in monitoring amphibian and reptile populations, especially those under threat or presumed to be declining. The book deals with issues of plot design, sampling design, enumeration methods, distribution and density assessment, and trend detection. Separate chapters deal with specific examples relevant to each major vertebrate group, including amphibians and reptiles. A dichotomous key to enumeration methods provides guidance as to the type of techniques appropriate to differing sets of survey aims and population characteristic assumptions.

Herpetological Bibliography of Indonesia, by Indraneil Das. 1998. Krieger Publishing Company, Krieger Drive, Malabar, Florida 32950, USA. 92 pp. Hardcover. US $22.50. ISBN 1-57524-026-2.

This bibliography lists the citations for approximately 1700 publications dealing with the amphibians and reptiles of the Indo-Malayan Archipelago. The area covered includes most of Indonesia (excluding Irian Jaya and associated smaller islands), as well as the Andaman and Nicobar Islands (India and Myanmar), Sarwak and Sabah (Malaysia), and Palawan and the islands of the Sunda Shelf (Philippines). The references, which include citations in at least 14 languages, extend from the 18th Century to 1997. Systematic, faunal, and natural history publications make up the bulk of the citations, although papers on other topics are also included. Although extensive bibliographies are available for some groups of the herpetofauna in some regions of the Indo-Malayan Archipelago, this small book provides the first comprehensive set of citations. Of particular interest are many citations from southeast Asian journals not widely known to herpetologists outside the region.

Interpretive Atlas of Texas Lizards, by Ralph W. Axtell. 1986–1998, *et. seq*. Privately published by and available from the author (Ralph W. Axtell, 2814 Rock Hill Road, East Alton, Illinois 62024, USA). Individual accounts available separately. Cost: US $0.10/page + postage and handling.

The most recent installment (number 18) in this series is *Holbrookia maculata*, the lesser earless lizard. This account totals 11 pages in addition to a detailed range map representing over 350 localities and ca. 1150 specimens. Axtell provides an in-depth discussion of distribution in Texas, along with current taxonomy, geographic variation, conservation status, and suggestions for future work.

ERRATUM

A recent Natural History Note on the diet of *Lepidochelys kempi* (Frick and Mason 1998. Herpetol. Rev. 29[3]:166–168) contains two errors. First, the third entry in Table 1, an adult female (63.5 cm CCL), was actually stranded on 8 June 1993, not 8 July 1993. Second, this same turtle appears in an earlier note (Frick 1997. Herpetol. Rev. 28[3]:149). This specimen's inclusion in Table 1 of the more recent note should have included a citation of the earlier publication.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Labeling within figures should be in 12 pt. sans serif font, such as Helvetica, Arial, or Geneva. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR Treasurer (Dr. Robert D. Aldridge; contact information on inside front cover) or from the SSAR web page (http://falcon.cc.ukans.edu/~gpisani/HRinfo.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 640		$340
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$190

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@sluvca.slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1999 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$50; Student membership $30; Family membership $60. Institutional subscription $95. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $30. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $25.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

1999 — Pennsylvania State University, University Park, Pennsylvania, USA, 24–30 June (Jay Stauffer, Chair).
2000 — Universidad Autónoma de Baja California Sur, La Paz, BCS, México, 14–20 June 2000 (Carlos Villavicencio, Chair).

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
1999 ANNUAL MEETING
together with
AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS
and
THE HERPETOLOGISTS' LEAGUE

24 – 30 June 1999
The Pennsylvania State University, State College, Pennsylvania, USA

Keynote Address: "HERPETOLOGIST IN THE MIST: MY LIFE AMONG THE GUERILLAS," by Jonathan A. Campbell, The Herpetologists' League Distinguished Herpetologist (University of Texas at Arlington).

Symposium: "VARIATION IN LIZARD SOCIAL BEHAVIOR: INDIVIDUALS, POPULATIONS, AND SPECIES."*Organizers:* J. Kelly McCoy, Biology Department, Angelo State University, San Angelo, Texas 76909, USA; e-mail: kelly.mccoy@angelo.edu; Stanley F. Fox, Zoology Department, Oklahoma State University, Stillwater, Oklahoma 74078, USA; e-mail: foxstan@okstate.okway.edu; and Troy A. Baird, Biology Department, University of Central Oklahoma, Edmond, Oklahoma 73034; e-mail: tbaird@aix1.ucok.edu.

Symposium: "LIZARD SYSTEMATICS AND EVOLUTIONARY BIOLOGY FOR THE NEXT MILLENNIUM: A SYMPOSIUM HONORING THE LIFE WORK OF RICHARD ETHERIDGE." *Organizers*: Robert E. Espinoza, Ecology, Evolution & Conservation Biology, MS 314, University of Nevada, Reno, Nevada 89557, USA; e-mail: espin_r@unr.edu; and L. Lee Grismer, Department of Biology, La Sierra University, Riverside, California 92515-8247, USA; e-mail: lgrismer@lasierra.edu.

Symposium: "AN *ANOLIS* SYMPOSIUM." *Organizers:* Manuel Leal and Jonathan B. Losos, Department of Biology, Washington University, St. Louis, Missouri 63130, USA (e-mail: mleal@biodec.wustl.edu and losos@biodec.wustl.edu); and Robert Powell, Department of Natural Sciences, Avila College, Kansas City, Missouri 64145-1698, USA (e-mail: powellr@mail.avila.edu).

SSAR Conservation Forum: "BIOLOGY AND CONSERVATION OF TURTLES IN THE GENUS *CLEMMYS*." *Organizers:* Sheila Tuttle (e-mail: stuttle@skidmore.edu) or James Harding (e-mail: hardingj@pilot.msu.edu).

Contributed Paper and Poster Presentations: There will be several concurrent sessions each day throughout the conference.

Student Paper Awards: Seibert Prizes (US $200 each) will be awarded in four categories: Systematics, Ecology/Evolution, Conservation, and Physiology/Morphology. Refer to the September 1998 issue of *HR* for details.

Student Travel Grants: Ten travel grants of US $200 each will be available for SSAR student members. Refer to the December 1998 issue of *HR* for details.

Multimedia Presentations: "HERPETOLOGY OF THE WEST" and "AMPHIBIANS OF THE APPALACHIANS" by David Dennis and Eric Juterbock; "HERPETOLOGICAL NAMESAKES" by Kraig Adler and David Dennis.

Social Activities: General Reception at the Penn Stater Conference Center, SSAR Auction, Barbecue, Graduate Student Reception, ASIH Banquet, and Frameable Art Silent Auction.

Field Trips: Carnegie Museums of Art & Natural History, Fallingwater, National Aquarium, New Jersey State Aquarium and Academy of Natural Sciences, Philadelphia Zoo and Academy of Natural Sciences.

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

Costs: Pre-registration US $235 regular, US $133 student, US $95 accompanying person. After April 23, 1999, costs are US $280 regular, US $185 student.

Further Details: Meeting Announcement and Call for Papers was mailed to all Canadian, U.S., and Mexican members of SSAR in December 1998. Overseas members wishing to receive this information may do so by contacting Janet Patterson, Senior Conference Planner, The Pennsylvania State University, 225 The Penn Stater Conference Center Hotel, University Park, Pennsylvania 16802-7002; tel. 814-863-5100; e-mail: ASIH99@cde.psu.edu. For information concerning program content, please contact: Jay Stauffer, School of Forest Resources, The Pennsylvania State University, 2C Ferguson Building, University Park, Pennsylvania 16802, USA; tel. 814-863-0645; e-mail: vc5@psu.edu. Please visit the meeting web site at http://www.outreach.psu.edu/C&I/ASIH/ for additional and updated information.

About Our Cover: *Lepidochelys olivacea*

A quirk of nature has created an oasis of sorts on the Pacific Coast at Playa Nancite, a beach in Santa Rosa National Park, Guanacaste Province, Costa Rica. Craggy rocks and thornscrub conspire to form an abrupt and forbidding barrier to the leeward side, while shuddering breakers discourage approach from the sea at Nancite. It is one of the few secret places where earth and ocean meet, and it hosts a spectacular, world-class display of wildlife: the great *arribadas* (nesting aggregations) of the most diminutive and numerous of all sea turtles—the *Lora* or Olive Ridley (*Lepidochelys olivacea*). Synchronous, massive swarms of turtles churn the smooth sand into tangles of serrate tracks during really big *arribadas*, a phenomenon known to occur on only five beaches around the world. Nancite is unique among them in that it is totally protected, by nature and by humans, making it the most significant of all marine turtle rookeries.

Theories abound as to why *Loras* alone among sea turtles nest this way. Perhaps it is to satiate their many predators—stealthy coatis, raccoons, and coyotes, lumbering spiny-tail iguanas, and skittering ghost crabs—by providing them with a surfeit of food, thus assuring survival for a critical few. Although the Nancite *arribadas* are more-or-less monthly, their occurrence is not entirely predictable, and we still do not understand the suite of prerequisites that precipitates their onset. From July through December, for up to a week around each third-quarter moon, *Loras* converge on Nancite in unprecedented numbers. As many as 8,000 turtles at a time clamber through the nearshore waters, bathed like fire opals in ghostly cascades of glitter as their struggles disturb the bioluminescent plankton in the surf. When this chelonian Woodstock is over, as many as 150,000 *Loras* may have left their eggs and efforts on the beach at Nancite. It is one of the earth's greatest and most unheralded events.

Sometimes, when the *arribada* is particularly large, emergence may begin in early afternoon, and the fortunate person present will witness a spectacle usually reserved for the darkness. On 20 November 1997, **Alejandro Solórzano**, a prominent Costa Rican herpetologist and Director of its National Serpentarium, was there. As the early arrivals splashed towards land, Solórzano photographed this *Lora* with a Canon EOS ELAN using a Canon 35–105mm zoom lens and Fuji Provia 100 film exposed at f/16 for 1/60th of a second. Alejandro's articles and photos have made him well-known to those interested in Central American natural history. His book, "Las Serpientes de Costa Rica: Gúia General de Identificación," featuring illustrations by Michael and Patricia Fogden, Louis W. Porras, and William W. Lamar, is being published by the Universidad de Costa Rica.

Separation and imaging of Solórzano's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

SSAR BUSINESS

SSAR Election Results

Results of the recent SSAR election are as follows:

President-elect (to serve as President for 2000) ..... *Julian C. Lee*

Secretary ..... *Ellen Censky (unopposed).*

Treasurer ..... *Robert Aldridge (unopposed).*

Directors ..... *Maureen Donnelly and Akira Mori.*

New Editor for SSAR Herpetological Circulars

John Moriarty has been appointed as Editor for the SSAR Herpetological Circulars, succeeding Joseph T. Collins. Individuals wishing to discuss possible projects for publication in this series should contact Moriarty at the postal address on the inside front cover or by e-mail at frogs@tc.umn.edu.

Proposed Amendment to the SSAR Bylaws

Members of the Society for the Study of Amphibians and Reptiles are hereby notified of a proposal approved by the SSAR Board of Directors to amend the following article of SSAR Bylaws to extend the term of office for several officers from one year to two or three years (dependent on position):

Article ll. Section 3 currently reads: "The terms of office for the President, President-elect, Secretary, Treasurer, Publications Secretary, and Immediate Past President shall be for one year; those for Directors shall be for three years (with election to provide for staggered terms so that no more than two Directors shall be elected in any one year)."

If amended, it will read: "The terms of office for the President, President-elect and Immediate Past President shall be for two years; those for Secretary, Treasurer, Publications Secretary and Directors shall be for three years (with election to provide for staggered terms so that no more than two Directors shall be elected in any one year)."

These proposed amendments will be on the agenda for discussion at the 1999 general business meeting at Penn State University on Sunday, 27 June at 1500–1630 h. A ballot on the amendments will be submitted by mail to the SSAR membership after the annual meeting at Penn State. The new terms would take effect in 2001 for those persons elected by mail ballot during 2000.

HR Staff Changes

The end of 1998 brought about several changes in the composition of the *HR* staff. Kathryn Vaughan has stepped down as Section Editor for Natural History Notes. This vacancy has been filled by Brian Hauge (Pennsylvania State University, Hazelton). Associate Editor Hal Avery has resigned, and has been replaced by Joe Mendelson (Utah State University). Liz Johnson, *HR*'s longtime ad manager, has resigned her position. On behalf of SSAR,

the editors thank Kathryn, Hal, and Liz for their service to the society and their colleagues.

Items Needed for SSAR Auction at Penn State

The SSAR Auction will once again be conducted during the annual meeting at Pennsylvania State University in June 1999. All proceeds from the auction go to the SSAR treasury, and help to continue the production of the diverse publications and services for which SSAR is known. Items of value, as well as those that lend themselves to humor, are always welcome. Following in the footsteps of Joe Collins and Darrel Frost, Dave Morafka will try his hand at removing large quantities of cash from auction participants through the judicious use of beer and plastic. Auction items may be brought directly to the meeting, or sent in advance to: *Janet Patterson, Conferences and Institutes, The Pennsylvania State University, 255 Penn Stater Conference Center Hotel, University Park, Pennsylvania 16802-7005, USA.*

Publications Needed for SSAR Graduate Student Reprint & Book Scavenge

Reprints and other publications are needed for the 1999 SSAR student reprint scavenge at Penn State. The graduate student social is greatly enhanced by the opportunity for students to acquire various herpetological literature. Now would be a good time to disseminate those extra reprints you have cluttering your office. Anyone wishing to donate items in advance may send them to: *Janet Patterson, Conferences and Institutes, The Pennsylvania State University, 255 Penn Stater Conference Center Hotel, University Park, Pennsylvania 16802-7005, USA.*

NEWSNOTES

Southwestern Research Station Positions And Grants For 1999

VOLUNTEERS—Approximately 30 volunteer positions are open in 1999 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 14 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SOUTHWESTERN RESEARCH STATION STUDENT SUPPORT FUND—The American Museum of Natural History awards several grants each year of approximately $400–$800 to graduate students or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona.

Information and application forms for this program and other Museum grant programs can be obtained by writing: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024-5192, USA. Application due date: February 15, 1999. Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SEASONAL OFFICE ASSISTANT—Assist in operations of biological research station office and nature shop: taking reservations, answering phones, greeting guests, supervising volunteers, etc. Begin March 14, 1999, through September 1999. Five-day week; salary $235/wk, plus room (shared) and board. Applicant must be punctual, organized, enjoy people, and be interested in living in a remote setting (Chiricahua Mountains) and working with biological researchers. Biological training an asset. Call and send résumé to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA. tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

Ernest A. Liner Scientific Collection

The Department of Herpetology, American Museum of Natural History, is pleased to announce that Dr. Ernest A. Liner of Houma, Louisiana (USA), has transferred his important scientific collection of amphibians and reptiles to our care. Accessioning this large collection will take time, but individuals who have questions about these specimens may inquire among Drs. Linda Ford, Darrel Frost, or C. J. Cole at the Department of Herpetology, AMNH, Central Park West at 79th Street, New York, New York 10024-5192, USA.

If you have an outstanding loan of specimens from the Liner Collection, please contact us immediately so that we can prepare updated invoices to reflect the transfer of the collection. If you are ready to publish on certain specimens, please contact us for AMNH catalog numbers for publication. Also, if you are ready to return specimens that are on loan to you, please return them directly to the AMNH after notifying us that the specimens are being sent. Please use e-mail specifically for these communications; addresses are lford or frost or cole@amnh.org.

Osteology Collection of Dr. Richard Etheridge

The Department of Herpetology, American Museum of Natural History, is pleased to announce that Dr. Richard Etheridge, San Diego, has transferred to the AMNH the major part of his osteological collection of amphibians and reptiles. Accessioning this large collection will take time, but inquiries for access should be directed to either Dr. Darrel Frost, Dr. Charles J. Cole, or Dr. Linda Ford at the Department of Herpetology, AMNH, Central Park West at 79th Street, New York, New York 10024-5192, USA.

Announcement: A Forum on the Biology and Conservation of Turtles in the Genus *Clemmys*

This forum, under the auspices of the SSAR Conservation Committee, will take place at Pennsylvania State University during the joint meeting of the ASIH, HL, and SSAR, 24–30 June 1999. The genus *Clemmys* presently includes four semi-aquatic species of North American turtles which, as a group, display varying degrees of habitat specialization as well as many unique behavioral and morphological adaptations. In addition, all have experienced significant recent population declines, and present an urgent challenge to researchers and wildlife managers to devise workable management strategies. This forum will include spoken and poster presentations from a wide spectrum of chelonian biologists and conservationists. Topics will range from basic biology (including population ecology, behavior, reproduction, and systematics) to reports on exploitation and protective legislation. The paper presentations will be followed by an open discussion session on the management implications of present knowledge, and possible directions for future research and conservation efforts.

For information on this event please contact the SSAR Conservation Committee (Michael Klemens, Chair; e-mail: mwklemens@aol.com) or organizers Sheila Tuttle (tel. 518-580-5073; e-mail: stuttle@skidmore.edu) or James Harding (tel. 517-353-7978; e-mail: hardingj@pilot.msu.edu). A tentative list of participants and titles is available on the Penn State meeting web site (www.outreach.psu.edu/C&I/ASIH/).

Fellowship in Herpetology: Prehensile-tailed Skink Project

The Philadelphia Zoo is seeking a qualified candidate for a fellowship in herpetology. The fellowship will be focused on obtaining a detailed morphometric analysis of the Zoo's prehensile-tailed skink (*Corucia zebrata*) captive population. For further information about the project, please contact Curator and Veterinarian of Amphibians and Reptiles, Dr. Kevin Wright (tel. 215/243-5373; e-mail: wright.kevin@phillyzoo.org). The qualified candidate should hold a bachelor's degree in the life sciences and be pursuing an advanced degree in herpetology or veterinary medicine. The duration of the fellowship is three months or one semester, and pays a stipend of US $1,500/month. Qualified candidates should submit a letter of intent, a curriculum vitae, and two letters of reference to Human Resources, Attention: Herpetology Fellowship, Philadelphia Zoological Garden, 3400 West Girard Avenue, Philadelphia, Pennsylvania 19104, USA. All applications must be received by 1 May 1998.

Collins Award Winner Announced

On 7 November 1998 at the Silver Anniversary Meeting of the Kansas Herpetological Society, Travis W. Taggart, first-year doctoral student at the KU Medical Center in Kansas City, was chosen as the first recipient of the Suzanne L. & Joseph T. Collins Award for Excellence in Kansas Herpetology. Taggart received his undergraduate degree at Fort Hays State University, a Masters Degree from Southeast Louisiana State University in Hammond, and is currently enrolled at the KU Medical Center in pursuit of a doctoral degree in molecular biology. At the banquet, James L. Knight, formerly of Salina and now with the South Carolina State Museum, representing The Center for North American Amphibians and Reptiles, joined KHS President John Lokke in presenting Taggart with a commemorative plaque and a check for US $1000.

The Collins Award is the largest biological award given annually in Kansas, and one of the largest awards given for research on reptiles and amphibians worldwide. Recipients of The Collins Award are selected from among those scientific presentations and papers that were given or published in the preceding two years (1996 and 1997). The award-winning paper published by Taggart in 1997 in KHS Newsletter 109 was entitled "Status of *Bufo debilis* (Anura: Bufonidae) in Kansas."

As provided for in the conditions of the award, at next year's meeting of the KHS in Pratt, Kansas, The Collins Award will be given for the best photograph of a native Kansas amphibian or reptile by a KHS member. The award alternates each year, with scientific research honored in even-numbered years, and photography in odd-numbered years.

Lani Burress, of Emporia State University, was honored with the Howard Kay Gloyd-Edward Harrison Taylor Scholarship for 1998, while Hank Guarisco, of Lawrence, and Kelly J. Irwin, formerly of Topeka and now with the University of Georgia Museum of Natural History, were the recipients of The Bronze Salamander Award, given for distinguished service to the Society, and Joseph T. Collins was installed as the fifth Distinguished Life Member of the KHS, joining Robert F. Clarke (Emporia State University), Henry S. Fitch (University of Kansas), Dwight R. Platt (Bethel College), and Hobart M. Smith (University of Colorado).

Carnegie Museum of Natural History-Collection Study Grants in Herpetology

The Carnegie Museum of Natural History is pleased to announce a grant to support herpetological research by graduate students and foreign scientists. The grant is intended to defray costs of transportation and lodging associated with visiting and using the collection. The Carnegie's herpetological collection contains more than 194,000 preserved specimens, including one of the largest collections of turtles and extensive holdings from the West Indies, Mexico, South America, Spain, Africa, India, and the Phillipines. Applicants should send the following, in duplicate: (1) a description of the proposed research (including its significance and the justification for visiting the Carnegie), not to exceed two pages, (2) literature cited, (3) budget, and (4) CV. Students should also arrange for two letters of recommendation to be sent. Awards will be made twice a year. Deadlines for application materials are 15 April and 15 November. Send applications to Collection Study Grants in Herpetology, Section of Amphibians and Reptiles, Carnegie Museum of Natural History, Pittsburgh, Pennsylvania 15213-4080, USA. For more information contact John J. Wiens (e-mail: wiensj@clpgh.org; tel: 412-622-5520; fax: 412-622-8837).

Publication Correction

In the recently published "A Key to Amphibians and Reptiles of the Continental United States and Canada," (University Press of Kansas, 1998), there is a significant transposition on page 99, left column, couplet 1. The correct couplet follows, and will be corrected in the forthcoming second printing:

1a. Ventral scales not transversely elongated (Fig. 205); eyes covered by scales 2
1b. Ventral scales transversely elongated (if barely larger than dorsal scales, divided into two rows with a midventral sulcus) (Fig. 205); eyes not covered by scales 3

MEETINGS

Meetings Calendar

13–17 May 1999—Fourth International Symposium on Isolated Vertebrate Communities in the Tropics, Bonn, Germany. Hosted by the Zoologisches Forschungsinstitut und Museum Alexander Koenig. To receive announcements and to obtain further information, please contact: Prof. Dr. W. Böhme, Adenauerallee 160, 53113 Bonn, Germany; tel. +49 228 91 22 250, fax ++49 228 216 979, e-mail: r.hutterer.zfmk@uni-bonn.de.

24–30 June 1999—42nd Annual Meeting, Society for the Study of Amphibians and Reptiles, together with The Herpetologists' League and the American Society of Ichthyologists and Herpetologists, State College, Pennsylvania, USA. (*Refer to meeting announcement on page 1 of this issue*).

6–10 September 1999—10th Ordinary General Meeting of the Societas Europaea Herpetologica, Natural History Museum of Crete (University of Crete), Irakleio, Crete (Greece). Deadline for abstracts and fees 31 May 1999. Contact: Natural History Museum of Crete, University of Crete, Knosou Av, 71409, Irakleio, Crete. Tel./fax +30 81 324 366; e-mail: nhmc_vtb@cc.uch.gr.

2–4 October 1999—Australian Herpetological Society, 50th Anniversary Conference on Captive Husbandry and Conservation of Reptiles, Sydney, Australia. (*Refer to detailed information below*).

5–9 October 1999—The Sixth Annual Conference of the Association of Reptilian and Amphibian Veterninarians, Columbus, Ohio, USA. For conference registration information contact: Wilbur Amand, VMD, PO Box 605, Chester Heights, Pennsylvania 19017, USA; fax: 610-892-4813.

8–11 October 1999—Second Symposium on the Status and Conservation of Florida Turtles, Eckerd College, St. Petersburg, Florida, USA. Contact: Gopher Tortoise Council, c/o George L. Heinrich, 1223 Alhambra Way S., St. Petersburg, Florida 33705-4620, USA; tel. (813) 865-6255; e-mail: highpine@gte.net.

12–17 December 1999—5th Latin American Congress of Herpetology, University of Uruguay, Montivideo, Uruguay. Abstract deadline 30 June 1999. For registration and information contact: Lic. José A. Langone, Secretario Ejecutivo V CLAH, Museo Nacional de Historia Natural, CC 399, 11000 Montivideo, Uruguay (e-mail: vclah@fcien.edu.uy). Within the U.S. or Canada, contact: Dr. Rafael de Sá, Department of Biology, University of Richmond, Richmond, Virginia 23173, USA (e-mail: rdesa@richmond.edu). Web site: http://zvert.fcien.edu.uy/clh.

Australian Herpetological Society 50th Anniversary Meeting

The Australian Herpetological Society will celebrate its 50th anniversary by hosting the Conference on Captive Husbandry and Conservation of Reptiles on 2–4 October 1999 in Sydney. Keynote speakers will be David Barker and Harold Cogger. The Conference will be open to anyone with a general interest in reptiles and amphibians, and invitations will also be extended to wildlife authorities, zoos, and museums. The general theme will be on captive maintenance and breeding and the role of amateurs, although interested participants are welcome to present papers of general interest. The first two days will include the presentation of papers while the third day will be a tour of a local zoological facility with a barbeque lunch. Other likely events are a conference dinner, post-conference field trip, photo competition, and more. For additional information contact Daniel Holloway (email: ozherps@zip.com.au) or visit the Society's web page (www.ozherps.zipworld.com.au).

OBITUARIES

James F. Lynch (1942–1998)

LINDA McCANN LYNCH
Smithsonian Environmental Research Center
P.O. Box 28, Edgewater, Maryland 21037, USA

James F. Lynch, Smithsonian Research Scientist, lost a long battle with cancer on 26 March 1998. He died at his home in Shady Side, Maryland, USA. Despite the difficulties of his illness, he carried out fieldwork in Texas only three weeks before he died. Over the past year, he produced several new papers and manuscripts and sustained an active correspondence with colleagues around the world.

Jim Lynch was a man with a great love of life and a large appetite for its many aspects. He was a productive scientist, a willing teacher, a talented artist, a gifted musician, and a generous friend.

Jim was born in Boston, Massachusetts in November 1942. He went to Harvard College, graduating cum laude in 1964 with a B.A. in geology. He was a man of many facets. To help put himself through school, he sang professionally with a group aptly named "The Lynch Mob." He also rowed during this period, and made the decision to concentrate on science rather than train as a member of the American Olympic rowing squad.

From Harvard, Jim moved to the University of California at Berkeley to pursue his Ph.D. It was at this stage that he underwent a major change in research direction. During his first two years at Berkeley he was a graduate student in Geology. After a summer geology work experience in a mine in Montana, he switched his major to Zoology, graduating in 1974. His thesis was titled "Ontogenetic and geographic variation in the morphology and ecology of the black salamander, *Aneides flavipunctatus*."

Jim then joined the Smithsonian Environmental Research Center in Edgewater, Maryland, as a research scientist. During his 24 years with the Smithsonian Institution, he conducted research in ecology, systematics, island biogeography, habitat reduction and fragmentation, and animal-plant interactions. Jim's conservation research in Central America and Mexico spanned over 30 years, from documenting the distribution of salamander populations in Guatemala to examining impacts of habitat fragmentation in Yucatan bird populations. Most recently, he initiated a project to monitor bird populations in the Laikipia District of Kenya, comparing avian communities in a variety of humanly impacted areas. Over the course of his career, he worked on amphibians,

birds, mammals, reptiles, and ants, and conducted research over an enormous range of the world, including North, Central, and South America, Australia, and East Africa, in addition to many parts of the United States.

Jim produced over 60 scientific publications. He was actively involved in many professional societies, advisory committees, and non-profit organizations. A regular reviewer for many international journals, he was an enthusiastic collaborator with scientists from all over the world.

In an attempt to support new scientists working in Conservation Biology, a fund has been set up in Jim's honor through the Smithsonian Environmental Research Center. The James F. Lynch Conservation Biology Fund will assist students and researchers working in Central America and East Africa, including students native to these areas. The goal is to build this fund into an endowment that will continue to help conservation biologists for years to come. Contributions and inquiries may be made to the James F. Lynch Conservation Biology Fund, c/o Jeanine Robert, Smithsonian Environmental Research Center, P.O. Box 28, Edgewater, Maryland 21037, USA. The first award for this fund will be made in 1999.

Benjamin Edward Dial (1944–1998)

HARRY W. GREENE
Section of Ecology and Systematics, Cornell University
Ithaca, New York 14853-2701, USA
e-mail: hwg5@cornell.edu

I first met Ben Dial at an amateur naturalists gathering in 1962, as he finished high school in Dallas and I began my senior year in Fort Worth. We were pals ever since those days in the Strecker Society, through lots of thick and a fair amount of thin, both of us fascinated by herpetology, music, people, and nature. Ben learned last August that his thyroid cancer, perhaps facilitated by years of daily immunosuppressants, had metastasized and was untreatable; he died at home on the afternoon of November 5th, accompanied by me, his dear friend Sue Lamoureux, and a hospice nurse.

As much as Ben and I both later came to love teaching, we were woefully mediocre undergraduates (all too easily distracted by newfound independence) and our professional paths were correspondingly indirect. He attended Texas A & M University in two bouts, interrupted by a few years of southern California surfing and work as a Houston zoo keeper, and finally received a B.S. in 1972. Ben received a masters from Texas A & M in 1975, with a thesis on geographic variation in *Coleonyx* supervised by James R. Dixon; he earned a Ph.D. from North Texas State University in 1981, with a dissertation on life history evolution in geckos supervised by Lloyd C. Fitzpatrick. Ben taught briefly at Texas A & M, then came to Chapman University as an assistant professor in 1984; he achieved tenure at Chapman in 1990, and was promoted to full professor in the spring of 1998.

Ben's scholarly contributions were primarily in physiological and behavioral ecology. He published about 20 scientific papers and book chapters, the first at age 17 (Dial 1961), and one chapter from his dissertation (Dial and Fitzpatrick 1983) was warmly praised by Stephen Jay Gould in a *Natural History* magazine column. After graduate school Ben turned to behavioral energetics, and conducted innovative research on the hatchling frenzy of baby sea turtles (Dial 1987) and limbless locomotion in reptiles (Dial et al. 1987). Recent publications include one of the first to analyze physiological ecology in the context of phylogeny and biogeography (Dial and Grismer 1992), as well as a clever study of chemoreception and buccal pulsing in geckos (Dial and Schwenk 1996). Ben's last manuscript was completed just days before he died, and when published will significantly advance our understanding of feeding energetics in snakes (I have reprints of most of his papers for distribution). Ben loved seeing and thinking about nature in the field, and perhaps the most insightful and lasting aspects of his scientific work stem from that perspective.

Ben earned two Distinguished Graduate Student Awards at Texas A & M University, and the Faculty Merit Award, two Hua-Cheng Faculty Fellowships, and a Research Excellence Award at Chapman University. His teaching evaluations were the best I've ever seen for anyone, anywhere, although by all accounts he was a hard task master and very tough grader. Ben was well organized, passionately interested in biology, thought it was really important to get things right, and truly liked people, especially young people. He delighted in devising tricks to capture students' attention, and especially to make them think. His colleague Michael Griffin told me that Ben sometimes set an upturned box next to jars of charcoal, salt, and water on the lectern, then began explaining that life was nothing more than a few simple chemicals. While students were still wondering what was going on, he suddenly lifted the box and exposed a Desert Iguana! No doubt many Chapman alumni—hopefully now influential lawyers, bankers, and so forth—will never forget the lesson of that beautiful and very lively lizard.

Two events are essential to understanding Ben and his impact on others. In about 1981, he befriended retired Texas businessman H. Erle Rawlins Jr., and from the transplant until Erle's death in 1995 (at the age of 87), they set an incredible example for anyone anxious about infirmities and aging. Late in 1985 Ben experienced shortness of breath and was diagnosed with myocarditis. After a year-long convalescence, during which his strength further declined, he was accepted in the transplant program at Stanford and received a new heart on March 21, 1987. Ben was an ideal patient because he carefully followed all medical instructions, yet resolutely lived as nearly as possible a normal life, despite various potential impediments. Seemingly oblivious to facial swelling and other drug side effects that would have severely threatened the vanity of some of us, he gave riveting public lectures on the surgery and its impact on his life (one talk was titled "I left my heart in San Francisco"). In the years following the transplant Ben and Erle explored the length of Baja California by car, and they conquered the difficult road to Batopilas, in the bottom of Mexico's Barranca del Cobre. They led memorable excursions for Chapman University students and alumni to Costa Rica and the Galapagos Islands, and laughed about once having driven the 6,000 mile "southern route" from Dallas to Orange County by way of Tikal, Guatemala.

As much as he loved the Southwest and Mexico, Ben was endlessly nostalgic about California and popular music. A movie version of his life would have to be filmed in La-La Land, with soundtrack by the Eagles and Fleetwood Mac. Although Ben frequently railed at widespread onslaughts against nature in Orange County, whenever I'd say something critical of the traffic, the smog, and so forth, he would start bragging about Brown Pelicans at Boca Chica Wetlands, near his condo. Ben found my upcoming move to New York unfathomable because, whatever the lure of exotic *travel*, he just couldn't imagine actually *living* anywhere other than California. And as for rock-and-roll, Janalee P. Caldwell wrote me that "Once when he visited us in Topanga, Ben and

Laurie [Vitt] started reminiscing about songs from the 60's and 70's; he knew all the lyrics to every song and Laurie could play the melodies. Probably every song from that era was sung that day!"

I don't want to obscure my friend's humanity with one-sided praise, especially since Ben laughed readily at his own foibles. He was zealously private in some respects, phenomenally picky, and even downright quirky about certain things; he could be irritatingly stubborn and judgmental. Ben was impossible to pigeon-hole politically, since his opinions spanned the reactionary to radical spectrum. Meals with him often veered into debates, whether or not anyone else really *wanted* to argue—usually about the environment, medicine, religion, or some other aspect of our human predicament. Ben disliked bullies and stuffed shirts, and he sometimes went out of his way to confront those he perceived, rightly or wrongly, as acting that way. Those things said though, for most of his associates, Ben was impossible not to like.

Ben left me several items on a computer disk that say a lot about him, including a list of "Some of my favorites: I love the music of Buffalo Springfield, the Byrds, Neil Young, 10,000 Maniacs, Eric Clapton, and Don Henley; the paintings of Georgia O'Keefe and Vincent Van Gogh; and the words of Robinson Jeffers, David Quamman, John McPhee, and Barry Lopez. I love soapberries collected in the fall and then back-lit, really weathered wood, green-glass insulators that are old enough to have a patina, the smell of wet Creosote Bushes, the colors of a Madrone, the antics of Desert Iguanas, everything about Gray-banded Kingsnakes, the fire-pit at Nepenthe, the cathedral at Chartres, the zócolo at San Miguel de Allende, the Study Butte Store in Big Bend, and the desert, any desert." Ben also loved Chapman University. He was proud of his students and colleagues, and he was extremely grateful for the support they provided in so many ways during his illnesses. Memorial donations can be sent to the Chair, Natural and Applied Sciences Division, Chapman University, Orange, California 92866, USA, where an undergraduate prize in biology has been established in honor of Ben and Erle.

I know from our conversations during his last few weeks that Ben was totally at peace with impending death, and that he wanted us to celebrate collective good fortunes rather than mourn his passing. Besides a legacy of inspired undergraduates and formal scientific accomplishments, Ben Dial left the unusual example of his profound joy, in the face of substantial physical hardships, for those things and places and creatures and people that he cared about. Ben once told me that the years since the heart transplant were by far his best, because since then he "always took time to smell the flowers." A common response of his friends, colleagues, and students to news of Ben's passing was how deeply important, how personally strengthening his example had been to them. The computer document he left me ends with this: "Here's my advice for young people, borrowed from Joseph Campbell's *The Power of Myth*. If you are after happiness, it works: 'Follow your bliss.'"

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Anne Maglia or Christopher Sheil; postal and e-mail addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are listed. The Web site address is:

http://www.sisna.com/users/Herpbooks/Contents.html

Social Monogamy and Paternity in *Tiliqua rugosa*

In this study, the authors investigate the social monogamy and paternity of *Tiliqua rugosa* by radio tacking 55 adult female and 39 adult male lizards during their spring activity period, for a

period from 1–5 years. The results of the radiotelemetry portion of this study indicate that social monogamy is the normal state for females, and seems to be the common pattern for males (18% of adult males showed polygyny). To investigate paternity of offspring, 21 gravid females were removed to the laboratory, where they gave birth to 42 offspring. Genotypes of five polymorphic microsatellite DNA loci were determined for the females, their male partners, and all offspring. Nineteen percent of the litters showed signs of extra-pair fertilization. A discussion of social monogamy and extra-pair mating is presented and the results of this study seem to support the hypothesis that social monogamy within a season results from male *T. rugosa* guarding female partners, and that males are constrained to monogamy because they cannot successfully defend multiple females. Eighty percent of the males in this study that were found to be socially monogamous were shown to have fathered all the young of their female partner.

BULL, C. M., S. J. B. COOPER, AND B. C. BAGHURST. 1998. Social monogamy and extra-pair fertilization in an Australian lizard, *Tiliqua rugosa*. Behavioral Ecology and Sociobiology 44(1):63–72.

Homeward Orientation in *Tiliqua rugosa*

Tiliqua rugosa is a monogamous skink that exhibits high pair fidelity. This study indicates differences between and among sexes in homeward orientation performance when males and females were displaced during three phases of the spring activity period (i.e., pre-pairing, during pairing or mating, and post-pairing periods). The author found all groups to be significantly oriented homewards during all periods, with the exception of post-pairing males; males were significantly better homeward oriented than females during the pairing period. Differences in homing motivation between the sexes are discussed.

FREAKE, M. J. 1998. Variation in homeward orientation performance in the sleepy lizard (*Tiliqua rugosa*): effects of sex and reproductive period. Behavioral Ecology and Sociobiology 43(4/5):339–344.

Phenotypic Plasticity in *Rana sylvatica*

The authors discuss hypotheses of phenotypic plasticity and comment on two major assumptions that accompany them. The first assumption is that plasticity improves the fitness of individuals and the second is that it evolved in response to selection imposed in heterogeneous environments. Though the authors agree that the second assumption is difficult to test, they state that it can be tested in a general form by determining whether natural selection currently acts to maintain phenotypic plasticity. In this study, the authors examined several plastic morphological traits in larval wood frogs (*Rana sylvatica*). Larval *R. sylvatica* were selected to be reared either in the presence of predators (dragonfly larvae [*Anax*] confined within cages to prevent actual predation), or in predator-free artificial ponds. Results show dramatic differences in size and shape between conditioning treatments, with the predator-reared larvae having relatively shorter bodies with deeper tails. Tests of mortality of predator-exposed larvae and predator-free larvae to *Anax* larvae also was examined and mortality was found to be greatest among larvae with relatively short, shallow tails and narrow tail musculature (i.e., those anuran larvae that were reared in predator-free ponds). According to the authors, their results indicate that morphological plasticity in larval wood frogs is promoted by selection and that they support the hypothesis that plasticity represents an adaptation to variable predator environments.

VAN BUSKIRK, J., AND R. A. RELYEA. 1998. Selection for phentoypic plasticity in *Rana sylvatica* tadpoles. Biological Journal of the Linnean Society 65(3):301–328.

Effects of Autotomy on Movement Patterns in *Psammodromus algirus*

Eleven adult lizards (*Psammodromus algirus*) (6 male, 5 female) were captured and taken to the author's laboratory to evaluate the costs and effects of caudal autotomy (i.e., loss of all but the proximal 2 cm of their tails) on escape performance before and after tail loss. The authors indicate that a control group of tailed lizards also was studied to determine the repeatability of locomotor patterns between trials. The authors found that tail loss had a significant effect on movement patterns as tailless lizards exhibited significantly slower speeds during bursts of locomotion and the distances traveled within these bursts were significantly reduced. They also found that pausing time increased and overall speeds dropped even greater than burst speeds. Loss of the tails also had the effect of decreasing main stride and significantly shortened escape distances. As there are many lizards that employ caudal autotomy as a defensive strategy, these results have relevance for the ecology and fitness of lizards that exhibit autotomy.

MARTIN, J., AND R. A. AVERY. 1998. Effects of tail loss on the movement patterns of the lizard, *Psammodromus algirus*. Functional Ecology 12(5):794–802.

Response of *Ambystoma talpoideum* to Clearcutting

The authors comment on the impact of forest management practices on amphibian populations and the attention that this topic has received over the past decade. They note that measured responses of amphibians to these changes only include comparisons of species diversity indices and population counts, thus lacking true spatial and temporal controls. In this experimental approach to test for differences in fecundity, growth rate, age at maturity, and whole-body storage lipids among individual *Ambystoma talpoideum*, 640 recently metamorphosed *A. talpoideum* were assigned randomly to four 100 m^2 field enclosures built in two habitats (recently clearcut patches and 40 yr old pine forests). After approximately six months of exposure to these habitats, the authors found no significant differences between habitats for number of recaptured salamanders, final body mass, final body length, percent whole-body storage lipid, clutch size, or percent storage lipid of eggs. Their results may suggest that

habitat modification of this sort (clearcutting) may not detrimentally effect newly metamorphosed *A. talpoideum*. The authors also discuss the inherent complexities in establishing the causal links between habitat management and effects on amphibians.

CHAZAL, A. C., AND P. H. NIEWIAROWSKI. 1998. Responses of mole salamanders to clearcutting: using field experiments in forest management. Ecological Applications 8(4):1133–1143.

Population Differences in Lizard Communicative Display

The authors describe the differences in the push-up displays produced by several populations of sagebrush lizards, *Sceloporus graciosus*, in Coyote Butte, Oregon (two populations) and Red Butte, Utah (one population). Lizards were observed during peak activity periods (0900–1200 h and 1400–1700 h) and care was taken not to bias data with pseudoreplication; however, the authors acknowledge that observations may be biased toward more active individuals. Results of this study indicate that the three populations studied differ in display body posture, number of legs extended to produce the up-and-down motion of display, and the number of headbobs produced in all three segments of the display (broadcast, courtship, and agonistic), and that push-up displays are undergoing far more rapid change than previously thought.

Structure, Function, and Evolution of the Oviducts of Squamates

The author discusses the diversity exhibited among extant squamates in the function of oviducts for fertilization, sperm storage, egg transport, eggshell deposition, maintenance of the early embryo, and the expulsion of the egg or fetus. Data from dissections of 30 genera, as well as data from literature, indicate seven macroscopic features by which squamate oviducts vary: extent and nature of regional differentiation; vascular supply; topographic asymmetry; number of oviducts; vaginal pouches; and relative positions of the cloaca. Specializations of the uterus are discussed and described for viviparous squamates, and include a discussion of specilizations for nutrient provision to the fetus. Results of a cladistic analysis of these data suggest that oviductal features in reptiles reflect evolutionary convergence and secondary simplification, rather than a unidirectional trend toward increased specialization.

Mechanics of Lung Ventilation in *Ambystoma tigrinum*

X-ray video and pressure measurements from the body and buccal cavities of the aquatic, larval *Ambystoma tigrinum* demonstrate that this salamander inspires by a two-stroke buccal pump, and that they exhale by actively contracting the hypaxial musculature. The author describes the mechanics of inhalation and employed electromyography to indicate duration and highest-amplitude activity for various muscles during the process of exhalation.

Correlations of Morphology, Ecology, and Evolution in Australian Suctorial Tadpoles

Suctorial anuran larvae use their highly specialized oral disks to adhere to the substrate in fast-flowing waters. Suctorial *Litoria nannotis*, *L. rheocola*, and *Nyctimystes dayi* were compared to pond-type larvae of *L. caerulea*, *L. genimaculata*, and *L. xanthomera*, as well as several other taxa from literature, to explore the diversity of cranial musculoskeletal structures to determine shared characters among taxa, irrespective of their phylogenetic position (suctorial tadpoles have evolved independently several times). Many chondrocranial and muscular characters are discussed and the authors conclude by stating that convergent evolution of many features shared among these taxa suggest that they are causally associated with the suctorial mode of larval life.

HAAS, A., AND S. J. RICHARDS. 1998. Correlations of cranial morphology, ecology, and evolution in Australian suctorial tadpoles of the genera *Litoria* and *Nyctimystes* (Amphibia: Anura: Hylidae: Pelodryadinae). Journal of Morphology 238(2):109–141.

Roger Conant to Turn 90 on May 6

RAYMOND J. NOVOTNY
Ford Nature Center, Mill Creek MetroParks
840 Old Furnace Road, Youngstown, Ohio 44511, USA
e-mail: raynovotny@yahoo.com

This writer is perhaps like many of you—one of the thousands of people fortunate enough to know Roger Conant. We know him through his books, his letters, or his friendship. Join with SSAR now to wish him a "Happy 90th Birthday" and reflect on a few of the highlights of his long, productive, and inspirational life.

Dr. Conant was born in Mamaroneck, New York on May 6, 1909, the only child of Charles and Clara Conant. At age twelve, when many youngsters are developing an interest in the creatures that hop, crawl, and slither, he tragically lost his father. His grandparents and other relatives helped his mother raise him. Fortunately, Roger, a good student not afraid of work, thrived. An Eagle Scout before age 15, he credits his experiences at Boy Scout camp, especially the capture of a copperhead, as the beginning of a lifelong devotion to herpetology.

Curator of Reptiles, Toledo Zoological Park (1930 or 1931). Photograph by H. K. Gloyd, courtesy of K. Adler.

Roger graduated from high school two years early and sought work in the zoo world and advice from luminaries such as Raymond Ditmars. A stint at the privately owned Twin Brook Zoo in New Jersey gave him his start and his direction. While not yet 20 years old, after two years of biology at the University of Pennsylvania, he secured a position at the Toledo Zoological Park in Ohio.

It would be difficult to underestimate the importance of his six years in Toledo for there he received his professional zoo training and exposure to academic herpetology. Beginning as curator of reptiles, he rose to the rank of general curator, in charge of the entire zoo. He took full advantage of opportunities at the University of Michigan in nearby Ann Arbor, with its faculty such as Alexander Ruthven and Frank Blanchard. It was at this time that Roger met Howard K. Gloyd, a UM graduate student who would become his lifelong friend and colleague.

Inspired by Ruthven's "Herpetology of Michigan," Roger decided to produce a similar study of Ohio. Despite the financial problems of the Great Depression, Roger and his young enthusiastic helpers criss-crossed the state and surveyed 86 of Ohio's 88 counties. Nine years after its inception, his study was published by the *American Midland Naturalist* as "The Reptiles of Ohio." This marked the first milestone of his impeccable reputation as a herpetologist.

Collecting water snakes in the Mississippi Delta, Louisiana (March 1948). Photograph courtesy of K. Adler.

Unfortunately, a difficult political situation in Toledo forced Roger to seek a new position and in 1935 he moved closer to home to Philadelphia, to the "Nation's First Zoo." He would spend the next 38 years there, beginning as Curator of Reptiles and retiring as Director. Although he was very busy during the workday overseeing the collections, promoting the zoo, and producing publications, he found the energy to continue to work on herpetological projects during his "off" time.

In 1951, Roger Tory Peterson approached Roger with an offer of a lifetime, the authorship of the Peterson field guide on reptiles and amphibians. For most of the 1950s, Roger and his wife Isabelle worked on this project, with Isabelle quitting her job in order to better contribute her photographic talent in addition to her loving support. This enormous project required the Conants to travel hundreds of miles to collect and photograph specimens. Thankfully, they received assistance from many interested herpetologists and naturalists across the country. Their commitment was rewarded by the universal acclaim given to the book after publication in 1958. The field guide has since been expanded and revised twice, in 1973 and 1991; the third edition was expanded in 1998. The combined editions are considered to be the most widely used books in herpetology and have sold over half a million copies.

Shortly before his retirement from the Philadelphia Zoo, the University of Colorado awarded him an honorary Doctor of Science degree. In 1973, he and Isabelle moved to Albuquerque and he was given a courtesy appointment as Adjunct Professor of Biology at the University of New Mexico. Unfortunately, Isabelle was stricken with cancer and passed away just three years later. Grief-stricken, he went to visit Howard Gloyd in Tucson, Arizona, who was also terminally ill. Roger promised to finish the monograph on the snake genus *Agkistrodon* that they had planned in the 1930s and worked on intermittently since.

Perhaps to assuage the pain he felt over his personal losses, he plunged himself into the daunting task. In 1990, SSAR published the book and it was immediately hailed as a classic by reviewers.

Roger's resume goes on for pages so here is just a sample. He has served as the President of the American Society of Ichthyologists and Herpetologists and he also was the unofficial adviser to the SSAR's predecessor, The Ohio Herpetological Society. Ten years ago, the American Association of Zoological Parks and Aquariums bestowed upon him its highest award, the R. Marlin Perkins Award. More recently, in 1995, the Roger Tory Peterson Institute of Natural History chose him for its Nature Educator of the Year Award. The following year, the Cleveland Museum of Natural History honored him with its David S. Ingalls, Jr. Award of Excellence.

Roger recently published his massive autobiography, "A Field Guide to the Life and Times of Roger Conant." The 500+ pages of this well-written and illustrated book document his life so far. It also serves as a history of twentieth century US herpetology, perhaps the only one we'll ever have. Although Roger will soon turn 90 we should not necessarily expect that his contributions and adventures are finished, for his family is known for its longevity. Just last fall he and his wife Kathryn Gloyd (Howard's widow) traveled again to South America and he now is completing a scientific paper on Mexican garter snakes.

Roger Conant with his recently issued autobiography. Photograph by R. Andrew Odum, Toledo Zoological Society.

Dr. Conant's support and encouragement of others is legendary. I first wrote to him when I was just barely a teenager and was amazed when he wrote back with a personal note, not a form letter. It has been almost 30 years since and we still keep in touch. I suppose in some ways he serves as a surrogate grandfather. No doubt many others have had similar stories.

With his abilities and focus, Roger Conant could have succeeded in any number of life pursuits. Those of us interested in amphibians and reptiles should be thankful that he shared our passion for these animals and shared himself with us for all these many years.

LETTERS TO THE EDITOR

Notes on the Type Series of *Oxybelis wilsoni* Villa and McCranie

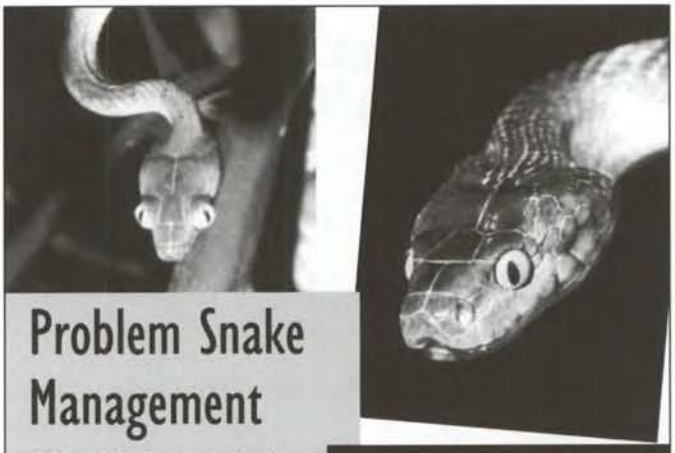
JAMES R. McCRANIE
10770 SW 164th Street, Miami, Florida 33157–2933, USA

Oxybelis wilsoni was recently described from Isla de Roatán, Islas de la Bahía, Honduras, by Villa and McCranie (1995). However, that paper contains numerous errors, due to inattention by the senior author to both the junior author's corrected versions of the manuscript and to the proofs. Nowhere are these errors more apparent than in the list of paratypes.

The list of paratypes begins with the inaccurate statement "Twenty-three males and 16 females ..." (Villa and McCranie, 1995:297). This statement is then followed by a list of 14 specimens in various museums (including the nonexistent number AMNH 00000). Following this list is the statement "In addition to these, we have donated 23 specimens to several museums for which we kdo [sic] not have accession numbers yet ...." This latter statement is erroneous on two counts. First there were not 62 specimens of *O. wilsoni* available to the authors as implied (data from 24 males and 18 females were used) and secondly, the statement is entirely untrue. In fact, at the time the description of *O. wilsoni* was published, apparently no specimens had been donated to museums. The word apparently is used because all efforts by McCranie to learn of the whereabouts of this material from Villa proved unsuccessful (all specimens collected by McCranie and Villa were entrusted to Villa to distribute to various museums). Additionally, personnel of two museums assigned numbers to specimens of *O. wilsoni* that Villa promised to send them (TCWC 67203–04; USNM 318010–12). As of this writing, these specimens have yet to be deposited in these collections, nor have efforts by personnel of these two institutions to secure this material from Villa been successful (R. K. Vaughan, pers. comm. 28 April 1998; G. R. Zug, pers. commun. 10 April 1998). This is especially troublesome because USNM 318010 was designated as the holotype and TCWC 67204 the allotype of *O. wilsoni*. Because Villa has not responded to correspondence, it is not possible to ascertain if this material is lost or is still in Villa's possession.

In late March of 1998, W. R. Courtenay, Jr., of Florida Atlantic University (FAU), found eight specimens of *O. wilsoni* in a room at FAU formerly occupied by Villa. Courtenay had earlier found several specimens that Villa had borrowed and that were designated as paratypes of *O. wilsoni* and returned these to their respective museums (LSUMZ 21768, 22365, 22374, 22398; TCWC 21914). The eight most recent specimens found by Courtenay were sent to L. D. Wilson, who gave them to me. This material was then deposited in several museum collections. As data for these specimens were used in the variation of the paratypes section in the description of *O. wilsoni*, these specimens should be considered part of the paratypic series (two, LDW 9170, 9196, were specifically mentioned in the section on variation in the paratypes). Pertinent data for this material are as follows (institutional acronyms follow those of Leviton et al., 1985): AMNH R-143507–08 (the latter formerly LDW 9170), TCWC 79732, Rocky Point near Santa Elena (town) on east end of Isla de Roatán, Honduras; TCWC 79731, USNM 521995 (the latter specimen was dehy-

drated when found by Courtenay), between West End and Sandy Bay, Isla de Roatán, Honduras; USNM 318011–12, 521996 (the latter formerly LDW 9196), near Coxen Hole, Isla de Roatán, Honduras. The numbers USNM 318011–12 were included in the list of paratypes by Villa and McCranie (1995) without locality data, and until now, without actual specimens tagged with these numbers.



As previously mentioned, the whereabouts of the holotype and allotype of *O. wilsoni* are unknown. Hopefully, Villa will soon realize his responsibility and send these specimens (if still extant) to their promised institutions. It is also to be hoped that Villa will donate the additional paratypes to an institutional collection as well.

Acknowledgments.—I thank W. R. Courtenay, Jr. for his efforts to locate specimens at FAU and L. D. Wilson for assistance with the specimens located by Courtenay and for reading an early draft of this manuscript. Wilson also sent several unanswered letters to Villa concerning the *O. wilsoni* and other material. I also thank the following people for answering my inquiries concerning the type series of *O. wilsoni*: C. J. Cole and L. S. Ford (AMNH); A. Resetar (FMNH); F. T. Burbrink (LSUMZ); R. K. Vaughan (TCWC); D. L. Auth (UF); and G. R. Zug (USNM).

Problem Snake Management

The Habu and the Brown Treesnake

EDITED BY
GORDON H. RODDA,
YOSHIO SAWAI,
DAVID CHISZAR, AND
HIROSHI TANAKA

Foreword by Harry W. Greene

A COMSTOCK BOOK
49 tables, 79 drawings,
30 photos $49.95

This book draws on intensive research on the Habu in Japan and Brown Treesnakes in Guam to present guidelines for snake management, offering a wealth of information on snake biology and behavior previously unavailable in English.

POINTS OF VIEW

Perils of Permits: Procedures and Pitfalls

WILLIAM E. DUELLMAN
Natural History Museum and Biodiversity Research Center
The University of Kansas, Lawrence, Kansas 66045-2454, USA
e-mail: duellman@kuhub.cc.ukans.edu

Permits to collect, permits to export, and permits to import have become an absolutely obligatory part of our lives. It makes no difference whether you are going to collect in the next county, the next state, or in some distant part of the world, almost without exception permits are required. The degree to which permits are required for collecting is indicative of the value ascribed to wildlife, which is a good thing for conservation of biodiversity.

Herein, I provide information and suggestions pertaining to the collection of scientific specimens in, and exportation from, foreign countries and their importation into the United States. A thorough summary of state regulations in the U.S. was provided by Levell (1997). My remarks are based on many years of collecting on four continents and focus on procedures for obtaining permits for preserved specimens—newly collected specimens, as well as those being loaned to, borrowed from, or exchanged with other institutions.

COLLECTING PERMITS

Each country has its unique set of regulations regarding the collection of scientific specimens. In some countries, such as the U.S. and Australia, each state has its own laws, and in some other countries, different regulations may pertain to certain parts of the country. Likewise, collecting in national (and sometimes state or provincial) parks and reserves commonly requires an additional permit. Obtaining these permits requires advanced planning, often many months in advance. It must be remembered that in-country biologists have to abide by the same regulations.

Many headaches and frustrations may be avoided by collaborating with a reputable colleague in the country to be visited. Many countries require that requests for collecting permits be made through a recognized institution or organization in the country, and a few countries (e.g., Brazil) require that special visas be obtained from a consular office. Such official requests may necessitate the inclusion of any combination of the following: names, nationalities, and photocopies of photo pages of passports; inclusive dates of proposed collecting; areas to be visited (sometimes quite specific); research proposal outlining the specific needs for specimens and the scientific significance of the project; numbers of specimens to be obtained and how they are to be collected and prepared; institutions in which specimens are to be deposited; and perhaps an application fee. (If the permit is not issued, you should not anticipate that the application fee will be refunded.) In non-English-speaking countries, the application should be written in the native language. It is not uncommon for the applicant to have to agree to take one or more in-country biologists in the field at the applicant's expense. Some countries require the applicant to present one or more lectures. Furthermore, copies of field catalogues, a report on the field studies, copies of photographs, and copies of all publications resulting from the field work may be required. Such collaboration provides the opportunity for working with scientists and training of students in the host country on their own biotas, thereby fostering their biodiversity

infrastructure and promoting local awareness of biodiversity and conservation.

Although in a few countries (e.g., Brazil and Costa Rica), provision of scientific permits is handled by an office staffed with knowledgeable biologists, most offices are within major government ministries, most commonly the Ministry of Agriculture or its equivalent. Personnel therein may include a zoologist, but more commonly they are agronomists or foresters by training, and sometimes they are simply political appointees having no background in biology. Generally, their mandate is to conserve the natural resources of the country, and most of their dealings are with commercial interests. Thus, a biologist who wishes to collect animals is challenging their mandate; it is up to the biologist to convince the officials of the necessity of documenting their national biota so that effective conservation measures can be undertaken. The herpetofauna in many parts of the world is poorly known; consequently, series of specimens are needed for systematic studies. Officials who issue permits are not systematists; they must be convinced of the necessity for collecting numerous individuals of many species. Perhaps in the not too distant future these offices will be staffed with personnel who have had the benefit of proper training provided by international collaboration.

Practically all of us who have dealt with such bureaucrats can document a variety of experiences. Some personal examples include: Before I took a group of students (US and nationals) into a previously unstudied area, an official in the permit office requested a list of the species and the number of individuals of each that we intended to collect; only after a lengthy explanation and my requesting her to provide me with a list of the names of persons working in an office building visible from her window did she understand the inappropriateness of her request. Another application was for the documentation of the herpetofauna at six sites; the office wanted to issue a permit for the collection of no more than four individuals of each species! Again, there is a need for education.

Making sure that the permit is correct before carrying out field work can save headaches. In one permit issued to me, the provinces in which we had permission to collect were listed. Upon being handed the permit, I noted that one requested province had been omitted, but I was told that the oversight was not important and not to worry. Upon my return to the capital with my collection and report of field activities, I was severely chastised for collecting in a province not listed on the permit. The person who told me that the oversight was not important could not be found! Once the Director of national parks passed through a field camp where intensive studies were underway on the flora and fauna; the director strongly encouraged us to send some of our team down river to make collections in a newly designated reserve. We did so at considerable expense and discomfort. Upon returning to the capital, we were informed by another official that we did not have permission to collect in the reserve, and the collections were confiscated. Of course, the Director of national parks was out of town. While working with colleagues from South Australia, we collected in Western Australia and returned to South Australia with the specimens. Officials in Western Australia were incensed; our permit was to "take," not "take out." The lesson is: Have everything in writing and be sure that the documents are correct and have all of the necessary signatures and seals.

Many countries require that a percentage of specimens be deposited in an institution in the country, and some countries (e.g., Brazil and Peru) require that all holotypes be deposited in such collections. Formerly, officials in some countries requested that a "synoptic collection" be left in the country. It was not uncommon for collectors to leave many specimens of common species and depart with the "goodies." Understandably, this probably was standard operating procedure in countries that had no herpetologists or herpetological collections. Nowadays, many such countries have trained, active scientists studying their herpetofaunas and maintaining scientific collections. If deposition of specimens in the host country is required, the most effective means of achieving this is to have an interinstitutional agreement that clearly documents the disposition of specimens, including percentage of specimens, division of taxa (and uniques), and disposition of types. Moreover, are the specimens to be left in the host country or returned after study? Obviously, such agreements should conform to the laws of the country, and it is best to have agreements approved by the office that issues permits.

Exportation of Specimens

Once field work has been finished, it is frequently necessary to spend several days in the capital city in order to obtain export permits. This usually is accomplished at the same agency that issued the collecting permit. Depending on the country, various kinds of information must be provided. Minimally, this will consist of a list of species and numbers of specimens of each, as well as the name of the person exporting the specimens and the institution in the U.S. where the specimens will be deposited. It is a good idea to have copies of your institutional import permit issued by the U.S. Fish & Wildlife Service (USFWS). At the time of applying for the export permit, it is necessary to have a document from the institution in the host country showing that all obligations regarding disposition of specimens and data have been fulfilled. Furthermore, additional costs may be entailed. For example, Cameroon charges a "kill tax" on each specimen; this is a spinoff from big-game hunting.

In addition to laws of a given nation, permit offices in all but a few nonsignatory countries theoretically abide by the regulations of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES). Species listed on CITES Appendix I can be exported (and imported) only with special permits, often from both countries. If such species are important to your research, it is imperative that you have the special permits. On the other hand, species listed on CITES Appendix II can be exported (and imported) with proper permits. Some foreign officials insist on using the official CITES exportation form for all species, whether or not they are listed by CITES.

In recent years, herpetologists have been collecting tissues for molecular studies. Whether such tissues are in liquid nitrogen or special liquid preservatives, it usually is necessary to have special permission for their exportation. With the increasing emphasis on pharmaceuticals from exotic plants and animals, nations around the world have increasing concern about their "genetic resources" and potential financial gain from commercial products derived therefrom. Thus, it may be necessary to sign restrictive documents.

All of these procedures may require what seems to be an inordinate amount of time; delays should be expected. Despite the fact that a neat, typewritten list of specimens was provided to the permit office, usually instead of an export permit with the list bearing appropriate official stamps being appended to the permit, everything may be retyped (with numerous errors) with faint carbon copies. Permits usually must be signed by a series of increasingly superior officials. Thus, once the permit has been prepared, several days may elapse before the last bureaucrat signs the permit.

A note of caution: Beware of dealing with individuals who act as brokers or who are representatives of nongovernmental agencies. Some of these persons might be very helpful, but other unscrupulous individuals charge substantial fees for their "services" and provide bogus documents. Also, from bitter experience, I learned that internal politics can cause grief. After having a reasonably good working relationship with an institution in a Latin American country for several years, a representative of a nongovernmental agency in that country coordinating a large collecting trip made a unilateral decision to have specimens deposited in another institution. Upon learning of this, the first institution pressured the government agency to negate the collecting permit and caused a delay of nearly one year in the issuance of the export permit.

Once the permit (and several copies thereof) is in hand, most of the procedure may be over. It is recommended that you transport your collection with you. If you are driving to the U.S. from a Central American country, you cannot transport specimens through Mexico to the U.S. without obtaining a permit from Mexico. Traveling by air may be less difficult, except for the costs of excess baggage and real, or perceived, problems with containers, especially a liquid nitrogen canister. However, it is possible that customs officials at the airport of departure will demand documentation for (and even inspection of) specimens. Enforcement of environmental and wildlife laws is a luxury that most nations can ill-afford. Thus, you may encounter officials who do not understand the legalities of your undertaking. This sometimes results in problems at airports.

If the specimens are being shipped via air or sea cargo, it is necessary to have a customs broker in the host country. The customs broker will need to have copies of the export and import permits, completed and signed USFWS declaration documents (Form 3-177), and name and address of a customs broker at a designated port of entry in the U.S. (see below.) If more than one container is being shipped, each container should be addressed properly and noted sequentially (e.g., 1 of 3 containers). A manila envelope containing copies of all documents should be securely fixed to the first container. Ideally, you should not depart the foreign country until the shipment has been fully taken care of and you have in hand a bill of lading. Otherwise, have a responsible colleague deal with the broker.

Laws in some countries require different documents for international shipments. For example, in order to ship specimens from Chile, a certificate from a veterinarian was necessary; the veterinarian to whom I took a container of preserved specimens opened the container, got a whiff of formalin, and with a very perplexed look on his face signed the document. As soon as possible, inform the intended customs broker in the U.S. of the scheduled time of arrival. Because of the time involved in seeing that a shipment is on its way and because of the fees charged by the broker, it usually is less expensive to carry the collection with you as excess baggage, unless the collection is extremely bulky or heavy.

Importation into the United States

There are only 14 designated ports of entry for importation of wildlife into the U.S.—Atlanta, Baltimore, Boston, Chicago, Dallas/Ft. Worth, Honolulu, Los Angeles, Miami, New Orleans, New York, Newark, Portland, San Francisco, Seattle. An Exception to Designated Port Permit may be requested from the appropriate USFWS Law Enforcement Regional Office—Portland, Oregon (503-231-6125); Albuquerque, New Mexico (505-248-7889), Fort Snelling, Minnesota (712-725-3530); Atlanta, Georgia (404-679-7057); Hadley, Massachusetts (413-253-8274); Denver, Colorado (303-236-7540); Anchorage, Alaska (907-786-3311). However, with an export permit from Mexico, specimens can be imported at the following border crossings—Brownsville, El Paso, Laredo, Nogales, and Tijuana.

Every person entering the U.S. must fill out a Customs Declaration Form, which includes a question about carrying animals or parts thereof; if you have any specimens, you are legally bound to answer "yes." Upon seeing that you have declared that you have animals, the customs inspector usually will ask what you have and then send you and your luggage to the inspector from the U.S. Department of Agriculture. Show the agricultural inspector the import permit and Form 3-177 with an attached list of species. The inspector nearly always will ask if any of the specimens are alive. At this point, any one of several things may happen: (1) The inspector may say that agriculture has no interest in these and approve your passage. (2) The inspector may agree to sign and stamp the importation documents and keep two copies to be forwarded to the USFWS. (3) Most correctly, the inspector will require your importation to be approved by an inspector from the USFWS. Often, a USFWS inspector is not present in the customs area; thus, the USFWS office must be called. In some cases, the matter can be handled over the telephone, and the USFWS records the institution where the material will be available for inspection, requests that the importation documents be mailed to their office, and will inform the agricultural inspector to approve passage. In other cases, the USFWS will send an inspector to the port of entry; this may result in your waiting for an hour or more. Upon his arrival, the inspector may do nothing more than review the documents and ask a few questions or carefully check every name against CITES lists and ask to see certain specimens. If the documents are not in order, the specimens may be confiscated.

In order to expedite the process at the port of entry, it is desirable to make previous arrangements with the USFWS at that port. These consist of providing the USFWS office there with the date and time of arrival and copies of import and export permits, Form 3-177 and a list of specimens. This usually cannot be done until shortly before you leave the foreign country, so it will be necessary to fax the documents. However, after going to the expense of faxing the documents, you cannot necessarily expect an inspector from the USFWS to be present when you arrive in the US.

If your specimens were not inspected at the port of entry and Form 3-177 was not signed by an inspector from the USFWS, you should notify your USFWS Law Enforcement Regional Office by sending a set of documents and informing the office of the location and availability of the specimens for inspection. There is an exception for the reporting after the fact that is available to "accredited scientists or scientific institutions" for the importation of "dead, preserved, dried or embedded scientific specimens or parts thereof" without initially filing Form 3-177. However, this form must be submitted within 180 days of the importation and must include taxonomic identifications of the specimens and their country of origin, together with a copy of the export permit from the country of origin.

The importation of frozen tissues of birds, as well as skinned study specimens not in fluid preservatives, requires a permit from the Animal and Plant Health Inspection Office (APHIS). APHIS regulates the importation of all "animal-origin materials" that could represent a disease risk to U.S. livestock and the importation and transportation of infectious organisms and vectors of disease agents, including not only animal products and byproducts but also biological materials that contain, or have been in contact with, certain organisms and animal materials (including cell cultures).

Although Agricultural Inspectors at a port of entry may pay special attention to frozen tissues, the APHIS regulations do not apply to amphibians and reptiles. Permits are issued to institutions approved by APHIS of the U.S. Department of Agriculture; inspection of storage facilities of such tissues is made periodically by officials from APHIS. Up-to-date information and application forms can be obtained electronically >http://www.aphis.usda.gov<.

In cases where specimens are shipped from a foreign country to a designated port of entry (or non-designated port with the prior Exception to Designated Port Permit), copies of all documents should be in the hands of the customs broker at the time of arrival of the shipment. Such shipments are subject to inspection at the port of entry, or they may be shipped in bond to your institution, where they may be inspected by a local agent of the USFWS.

Although many wildlife regulations and statutes seem to be overly complicated, they are the result of international treaties and agreements and must be followed. Minimally, every scientist involved with the importation and exportation of scientific specimens should be familiar with the U.S. Endangered Species Act (ESA), which is the U.S. statute that fulfills our obligations under the CITES Treaty. Full information about these regulations may be obtained from the Code of Federal Regulations. See especially 50 CFR, parts 13, 14, 16, 17, 18 and 23. The regulations are available electronically: >http://www.access.gpo.gov/nara/cfr/index.html<. Also see Digest of Federal Laws of Interest to the U.S. Fish and Wildlife Service: >http://www.fws.gov<. Information on CITES can be obtained electronically: >http://www.wcmc.org.uk:80/cites<. The CITES Appendices with the listing of controlled species and a listing of institutions can be accessed: >http://www.unep.ch/cites.html<. Also, essays and material on regulations included in Anonymous (1997) are useful.

International Loans, Exchanges, and Gifts

By strict letter of the law, all importation and exportation of wildlife must be documented for, and approved by, the USFWS. These regulations apply to specimens temporarily imported as a loan. Thus, if specimens are borrowed from a foreign institution, they must be documented as being exported and imported legally; moreover, if the species is listed by CITES, the CITES permit from the foreign country is required. For example, at The University of Kansas, we fill out Form 3-177 and attach a copy of the loan invoice from the foreign institution for a loan to us. When the specimens are returned, we fill out Form 3-177 and attach a copy of our shipping invoice. If specimens are loaned to, or exchanged with, a foreign institution, the same procedures are followed. Semiannually, all such documents are sent to the regional office of the USFWS.

Sometimes an institution receives specimens as an unsolicited gift from a person in a foreign country. Notification of such receipt should be sent to the local office of the USFWS. An attempt should be made to obtain the necessary permits from the person who sent the specimens. If no permits are forthcoming, the USFWS should be requested to rule on the status of the specimens. Once that is done, one of three things may happen:

- If the only problem involved is that of the filing of Form 3-177, the USFWS normally will allow you to file the form after the fact, because the material was an unsolicited gift.
- If the specimens required an export permit or other documentation from the country of origin, you should request, or ask the sender to request, an after-the-fact permit from the appropriate office in the country of origin.
- If you are not interested in keeping the specimens or the foreign government will not issue an after-the-fact permit, the USFWS will either allow the specimens to be returned to the sender or the items will be seized by the USFWS. Seizures of such material normally are settled with their abandonment by the receiver.

During an investigation, the USFWS may sequester all specimens under investigation. Upon the completion of an investigation, the specimens may be returned to the collection, confiscated, or returned to the country of origin.

Institutional Responsibilities

Collections in natural history museums are acquired by field collecting, exchange, gift, purchase, bequest, contract, abandonment, or other means. It is the responsibility of the institution to insure that all accessioned specimens were acquired legally. Because accessioning of material into the museum initiates ownership and legal responsibility, specimens should not be accessioned until all proper documentation is in order. If not already in place, formal policy and guidelines for the accessioning of specimens should be established in every natural history museum. As a model for aiding in compliance with accession policies, I present herein the accession checklist adopted by the Natural History Museum at the University of Kansas in April 1996.

Receipt of specimens previously catalogued in another museum (by donation, gift, exchange, abandonment, or purchase):

- Transmittal form or letter from appropriate authority at the institution of origin
- Signed Deed of Transfer form
- Export permit (if from a non-US institution)
- Import permit (if from non-US institution)
- CITES permits if transaction involves CITES-listed species
- APHIS certification (if applicable)

Receipt of specimens not previously catalogued in another museum (field work, gift, exchange, purchase, donation, bequest, or contract):

- Original or copy of collecting permit(s)
- Original or copy of export permit (if from foreign country)
- Signed Deed of Transfer form
- Current USFWS permit on file
- Copy of USFWS Form 3-177 (if from foreign country)
- CITES permits (if transaction involves CITES-listed species)
- Antarctic Conservation Act permit (if applicable)
- Bald Eagle Protection Act permit (if applicable)
- Bureau of Land Management permit (if applicable)
- Controlled Substances Act permit (if applicable)
- Feather Import Quota permit (if applicable)
- Federal Noxious Weed Act permit (if applicable)
- Fur Seal Act permit (if applicable)
- Marine Mammal Protection Act permit (if applicable)
- Migratory Bird Treaty Act permit (if applicable)
- Plant Pest Act permit (if applicable)
- Plant Quarantine Act permit (if applicable)
- State collecting permit (if applicable)
- USFWS Salvage permit (if applicable)
- APHIS certification (if applicable)
- Original or copy of field notes for specimens in accession
- Originals or copies of any correspondence relating to accession

The Deed of Transfer includes a description of the accession and a signed and dated agreement: "I hereby acknowledge that I have read the terms of acceptance of this accession, and that to the best of my knowledge, the specimens and/or objects comprising this accession were obtained legally."

Personal Responsibilities

Regardless of one's opinion or assurances from others, ultimately it is the individual's responsibility to know and abide by the laws and regulations of the country in which you are collecting specimens. Also, it is the individual's responsibility to know and abide by the laws and regulations of the U.S. and how your collection must be documented prior to importation. Anything less will expose the individual and the institution to possible criminal or civil penalties.

I have had the misfortune of being subjected to a Federal investigation. As a curator in the Division of Herpetology in the Natural History Museum at The University of Kansas, I collected thousands of specimens of amphibians and reptiles in various parts of the world. I thought that I was fairly knowledgeable about the wildlife laws and regulations of the U.S. and the foreign countries in which I was collecting. Unfortunately, I became lax in my observance of these laws and grew to depend too much on others to assist me in the tedious job of obtaining foreign permits and doing the required paperwork. My lack of foresight and negligence eventually contributed to a Federal investigation of me and The University of Kansas. The investigation dealt with five collections of amphibians and reptiles that I imported into the U.S. and one unsolicited collection that I received from a colleague. These six collections were imported into the U.S. between the years 1991 and 1994 without the required foreign permits and without declaring the items once they entered the U.S.. I did work with the USFWS on one of those importations in trying to obtain the required export permits after the fact. However, my lack of concern for the requirements of Federal wildlife laws of which I was aware led to eventual enforcement action against me. I was fined a substantial civil penalty (many thousands of dollars), was restricted from any collecting activities for one year, and was required to submit this paper in an effort to prevent others from making the same mistakes that I made. This investigation also resulted in a great deal of embarrassment and scrutiny of myself and The University of Kansas. Although I was acting as an agent of The University of Kansas and the specimens were deposited in that institution, the University placed all responsibility on me.

Thus, I encourage anyone involved with the collection of foreign scientific specimens for eventual importation into the U.S. to know and abide by the laws before acting. Do not depend on other individuals or your institution to assume those responsibilities. Educate yourself on the legal way to conduct your collecting and research activities. The laws are in place for purposes of biological conservation and must be observed if scientific collecting is to be a respected and continuing practice.

Laws and the Future of Scientific Collecting

In well-meaning efforts to protect species and certain populations, international organizations and governments throughout the world have enacted a bewildering array of regulations that commonly restrict scientific activities that are essential to secure the very information that might be useful in determining how to protect threatened species. Yet habitat destruction and wanton slaughter of animals continues. How many of us have returned to a formerly pristine forest only to find it cleared? How many of us have seen a person kill a rare snake but not be able to preserve the specimen for science because we had no permit?

We are all aware of species of amphibians and reptiles that are threatened or endangered, as we are aware of rapidly declining populations of amphibians. These so-called threatened and endangered species are listed in different places by different organizations; the listings do not necessarily coincide. Anyone using these lists needs to realize the different purposes of these lists and the legal requirements facing anyone conducting scientific collecting of these species.

A comparison of the three most common up-to-date lists of amphibians (ESA, CITES, and IUCN) reveals that only four species are common to the three lists (Duellman, 1999). The reason is that these lists have different purposes. The list generated by the Endangered Species Act, U. S. contains all of the federally listed endangered species of animals and plants. The species listed therein are protected under federal laws and regulations and can be imported into, or exported from, the U.S. only with a permit for scientific purposes obtained beforehand from the USFWS. The Convention on the International Trade in Endangered Species (CITES) has a list of species that are in peril of becoming endangered or threatened because of exploitation through international trade. Although these species can be imported into the U.S., their importation requires permits from the exporting country and sometimes from the U.S., as in the case of species listed on Appendix I. The list provided by the International Union for the Conservation of Nature (IUCN) is in place to help ensure that trade in wildlife is maintained at sustainable levels and in accordance with domestic and international laws and agreements. In many cases (e.g., dendrobatid frogs), listing by CITES has not curtailed traffic, because of commercial interests (Gorzula, 1996). International importation and exportation by the pet trade is in orders of magnitude greater than that by scientific institutions. Lobbying efforts by organizations such as the Pet Industry Joint Advisory Council are far more influential than any organization representing biologists studying biodiversity. These and other issues were addressed thoughtfully and eloquently by Campbell and Frost (1994).

In order to gather essential data on biodiversity, scientific collecting needs to be encouraged, and scientific collectors need to become thoroughly educated on the laws regulating their activities. Scientists need to take an active role in working with governments to establish regulations. In fact, scientists recently had the opportunity on the development of policy for the use of permits as conservation tools (Federal Register Notice, Vol. 63, No. 153, August 10, 1998). Moreover, biologists, especially systematists, need to educate the public and governments on the necessity of continued scientific collecting.

Acknowledgments.—I thank D. A. Carr, J. A. Campbell, W. R. Heyer, R. F. Inger, L. Krishtalka, W. W. Lamar, M. G. Medina, L. J. Vitt, J. E. Simmons, and L. Trueb for reading earlier versions of this manuscript and for their efforts in getting my message across effectively, but I have been unable to include all of their comments.

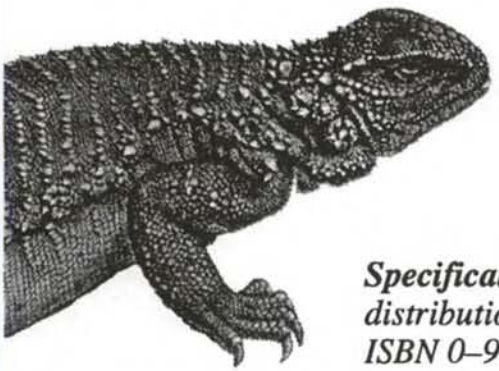
THE LIZARDS OF IRAN



by Steven C. Anderson

CALIFORNIA ACADEMY OF SCIENCES AND UNIVERSITY OF THE PACIFIC

IRAN IS A LARGE AND STRATEGICALLY LOCATED country, but few synthetic studies of its herpetofauna have been published. Steven C. Anderson has conducted extensive field work in Iran, beginning in 1958, and has spent a lifetime studying its herpetofauna, a subject on which he is a recognized authority. The lizard fauna of Iran is quite diverse and includes representatives of eight families: Agamidae (20 species), Anguidae (2), Eublepharidae (3), Gekkonidae (39), Lacertidae (42), Scincidae (14), Uromastycidae (3), and Varanidae (2).

This book is the first monographic treatise on the lizards of Iran, and contains sections on the history of herpetological studies in Iran; the biogeography of Iranian lizards; illustrated keys to families, genera, and species; an extensive bibliography of Iranian amphibians and reptiles; and appendices listing specimens examined and a gazetteer of collecting localities. The detailed species accounts include these sections: synonymy, diagnosis, color pattern, size, natural history, habitat, distribution, and remarks.

A major feature of this book is an outstanding group of color portraits of lizards (152 photographs) and their habitats (38). Most of these have not been published previously and many of the species of lizards have never been illustrated before. There are also nearly 150 figures in the text plus 103 spot distribution maps. This book will become the standard reference on the lizards of Iran and adjacent regions.

Specifications: *About 350 pages, 137 figures, numerous illustrations in keys, 103 distribution maps, 190 color photographs, index, clothbound with dustjacket, ISBN 0–916984–49–4. To be issued in September 1999.*

Two closely related skink (*Eumeces*) species have been recorded in the Inyo and White mountains of eastern California. Gilbert's skinks (*E. gilberti*) occur in both ranges around springs and streams between 1200 and 2400 m, and away from water between 1800 and 2400 m (Macey and Papenfuss 1991). Until 1991, only a single western skink (*E. skiltonianus*) was recorded in the Inyo-White range, although it has been presumed to be a high-elevation species inhabiting the pinyon-juniper (*Pinus-Juniperus*) woodlands of the White Mountains between 2100 and 3000 m (Macey and Papenfuss 1991). The distribution of both species in the Great Basin is likely influenced by the desiccation of the region since the last Pluvial period of the Pleistocene (Banta 1962). Where the two species come in contact, *E. gilberti* apparently occupies lower elevations and more arid conditions (Rodgers and Fitch 1947; Tanner 1957).

Little is known about these species in areas of sympatry. Furthermore, habitat use by the species has only been anecdotally described for most of their range. Both species seem to have similar preferences for open, rocky areas with scattered vegetative cover (e.g., Rodgers and Fitch 1947; Tanner 1957, 1988). The purpose of our study was to describe the microhabitat relationships of these skinks in a zone of sympatry in the Inyo-White mountains, Inyo County, eastern California.

The Inyo-White mountains, ranging from 1500 to 4200 m in elevation, lie along the California-Nevada border, parallel to and east of the Sierra Nevada Mountains. The environment is arid with warm, dry summers. Snow cover and rainfall usually last from November through May, and scattered thunderstorms occur in late summer (see Morton et al. 1995 for details). We worked in the pinyon-juniper (*Pinus monophylla-Juniperus osteosperma*) woodland. The understory was composed of scattered individual trees and small patches of only a few shrub species, most commonly sagebrush (*Artemisia nova* and *A. tridentata*) and bitterbrush (*Purshia tridentata* and *P. glandulosa*). The grass-forb layer was sparse and the ground cover was bare soil or rocks (Hall 1992; Lloyd and Mitchell 1973).

We established three trapping grids as representative of the pinyon-juniper vegetation in which the skinks were thought to be sympatric: "Pinyon" (T7S, R35E, sec. 29; 2100 m elevation) and "Cedar" (T7S, R35E, sec. 32; 2200 m elevation) were about 1.5 km apart, and "Westgard" (T8S, R35E, sec. 9; 1900 m elevation) was about 7 km from the other two. Grids were >300 m from a road. Each grid consisted of 41 pitfall traps (without drift fences) arranged in a 200 x 200 m (4 ha) area. We established nine parallel trap lines with traps placed at 25-m intervals. Traps were constructed of two no. 10 cans taped together (the bottom of one can was removed), with small (1–2 mm) drain holes punched in the bottom. A 30 x 30-cm piece of plywood was raised about 4 cm above each trap to provide shade (Corn 1994).

Traps were opened during the first week of May and closed during the last week of September for a total of about 5300 trap days per grid per year, from 1989 to 1991 (48,000 total trap days for the study). Traps were examined at least every two days. All captures were identified as to species, sex, and age, and a single hind toe—unique to each year of study—was clipped to facilitate determination of the number of animals captured. Animals were released >2 m from the trap. Identification of animals, including juveniles, was made following Macey and Papenfuss (1991). Morrison and Hall (in press) reported other, non-skink species captured.

To describe the joint distribution of animals on each grid we calculated the percent of traps occupied by at least one individual of both species in the same year, and in different years. The sample size of available traps (denominator in the calculation) was the number of different traps occupied by either species within or across all years, respectively.

We established 10-m-radius plots centered on each trap location to characterize the macrohabitat conditions surrounding a trap. Within each plot we determined the slope, aspect, and slope position (on a scale of 0.0–1.0, where 0 = bottom, 0.5 = mid slope, and 1.0 = ridge top); and counted snags (≥1.5 m tall), stumps (<1.5 m tall), and pinyon and juniper trees by height class (1.5–3, >3–6, >6 m). We also established a transect bisecting the 10-m-radius plot, and at 1-m-intervals along this transect, recorded the presence of habitat features that intercepted an imaginary line extending vertically above the ground. Features recorded included type of ground cover (e.g., bare ground, sand, gravel, and litter), dead and down woody cover, and the presence of each plant species within three height classes (given above).

We used one-way analysis of variance (ANOVA) and Tukey's multiple comparison tests to compare habitat use between the two skink species and the abundance of the habitat features on the study plots. Variances were equal across groups. Too few animals were captured for analyses by individual grids, or for the use of multivariate statistics (Morrison et al. 1992:329–330). We reduced the data set for presentation by conducting simple correlations among all variables and retaining one of each pair of variables with an $r > 0.4$ ($P < 0.05$); the variable retained had the lowest t-value of the pair. All analyses were conducted using SPSS-PC software.

Over all three years we captured 26 *Eumeces gilberti*, five of which were recaptures; 88% were adults and 12% were juveniles. Animals were captured between 25 May and 18 September. We captured 29 *E. skiltonianus*, one of which was a recapture; 52% were adults and 48% were juveniles. Animals were captured between 7 May and 19 September. *Eumeces skiltonianus* was more numerous on the Pinyon (5 *E. gilberti* and 11 *E. skiltonianus*) and Cedar (11 *E. gilberti* and 15 *E. skiltonianus*) grids, and *E. gilberti* were more numerous (10 animals) than *E. skiltonianus* (3 animals) on Westgard.

There was no overlap in trap use by the species in the same trap in the same year on Pinyon (0 of 10 potential traps); however, 9.5% (2 of 21) of the traps on Cedar, and 22.2% (2 of 9) on

TABLE 1. Habitat characteristics of trap sites used by *E. gilbeti* and *E. skiltonianus*, and the abundance of those characteristics, in the Inyo-White mountains, California, 1989–1991 (sample sizes in parentheses). Means with different letters were significantly different ($P < 0.05$), and those with letters in parentheses were nearly significant (i.e., $P < 0.1$), using Tukey's multiple comparison tests. All variables are percent cover except slope position (0 = bottom, 0.5 = mid slope, 1 = ridge). Only variables with mean values of ≥5% cover are presented.

Characteristic	*E. gilberti* (19) mean	SD	*E. skiltonianus* (23) mean	SD	Abundance (123) mean	SD	P[a]
Slope position	0.12B	0.06	0.66A	0.28	0.50A	0.35	<0.001
Slope (degrees)	13	7.1	15	10.0	15	7.0	0.550
Coarse gravel	50(A)	21.3	46(A)	23.3	58(B)	26.4	0.075
Large stones	8	9.8	6	5.5	5	7.7	0.209
Grass	6	5.1	5	5.7	4	5.4	0.332
Juniper litter	1(A)	4.1	1(A)	4.6	6(B)	11.7	0.056
Shrub litter	13A	11.0	12AB	10.7	7B	8.8	0.014
Total juniper trees	7	11.1	4	6.7	9	12.2	0.133
Total pinyon trees	30	16.5	33	22.3	26	19.0	0.316
Down wood	7	5.9	6	6.8	6	7.1	0.794

[a] Analysis of variance.

Westgard captured both species. Animals caught in the same trap but in different years were 7.7% (1 of 13) on Pinyon, 23.5% (4 of 17) on Cedar, and 25% (1 of 4) on Westgard.

Traps used by *E. gilberti* and *E. skiltonianus* had similar habitat characteristics, with slope position of capture sites being the only variable that was significantly different between species (Table 1). The similarity in habitat use by these species occurred despite considerable variability in habitat characteristics available to them. *Eumeces gilberti* were captured near the bottom of slopes, whereas *E. skiltonianus* were captured just above mid-slope. As slope position of traps increased, the cover of small juniper and coarse gravel decreased (r = -0.3 to -0.4, $P < 0.01$); whereas the cover of pinyon trees and large rocks increased (r = 0.2–0.3, $P < 0.05$). Thus, lower slopes were more open—and thus perhaps warmer—than the more shaded and protected mid-slopes. Relative to the abundance of habitat characteristics, both skink species were captured in locations of relatively greater shrub litter (Tukey's $P < 0.1$ for *E. skiltonianus*), less juniper litter, and less coarse gravel (Table 1). The use of deep litter for burrowing is typical of these species (e.g., Macey and Papenfuss 1991; Rodgers and Fitch 1947). Locations with a high proportion of juniper tend to have little litter cover and are sparsely vegetated (pers. obs.).

Eumeces gilberti were captured more frequently than *E. skiltonianus* on the Westgard grid, which was the lowest elevation grid and was relatively more open and had a high proportion of juniper trees (Morrison and Hall, in press). In contrast, *E. skiltonianus* outnumbered *E. gilberti* on the Pinyon and Cedar grids, which were more mesic due to an extensive cover of pinyon trees and a more easterly aspect (Morrison and Hall, in press). Banta (1962) speculated that *Eumeces* was more widespread in the Great Basin during the wetter, Pluvial periods of the Pleistocene. Further, he thought that *E. gilberti* was more capable of existing at lower elevations and in more arid environments than *E. skiltonianus*, which is restricted to higher elevations in southern mountains. Similarly, Rodgers and Fitch (1947) described *E. skiltonianus* as spotty in occurrence and restricted to cooler, higher areas in the Great Basin (see also Tanner 1957). Macey and Papenfuss (1991) speculated that *E. skiltonianus* was not found below 2100 m in the Inyo-White mountains. In contrast, they felt that *E. gilberti* occurred across a wider elevational range, from 1200 to 2400 m. Thus, our field sampling supported the basic relationships proposed by Banta (1962) and Macey and Papenfuss (1991). In addition, our results indicate that *E. gilberti* and *E. skiltonianus*, while broadly overlapping on the landscape level, tend to separate by microhabitat features (e.g., slope position, tree density) that may reflect microclimate conditions within their area of sympatry in the Inyo-White mountains.

A potential weakness of our study was the use of a single sampling method to assess skink abundance and habitat use. We could not conduct visual encounter surveys (Crump and Scott 1994) because our grids were part of a long-term study of small mammal ecology, and we wanted to minimize site disturbance. However, we also found both skink species to be rare during visual encounter surveys in other locations in the pinyon-juniper woodland (see Morrison and Hall, in press).

Acknowledgments.—We thank the personnel of the White Mountain Research Station (University of California), especially E. Phillips and D. Trydahl, for logistical support. We also thank all of our field assistants, including L. Baker, J. Block, L. Ellison, A. Mellow, and S. Shoemaker. We also thank R. A. Seigel and T. J. Papenfuss for comments on an earlier draft.

The "Spring Lizard" Bait Industry in the State of Georgia, USA

JOHN B. JENSEN
Georgia Department of Natural Resources
Nongame-Endangered Wildlife Program
116 Rum Creek Drive, Forsyth, Georgia 31029, USA
e-mail: john_jensen@mail.dnr.state.ga.us

and

CHUCK WATERS
Georgia Department of Natural Resources, Game Management Section
2150 Dawsonville Highway, Gainesville, Georgia 30501, USA

The term "spring lizard" is a colloquialism used by residents of the Appalachian Mountain region and refers to salamanders sold as bait for fishing. Obviously, this contradictory synonymy can create confusion for fishermen and bait dealers when communicating with biologists and wildlife agency personnel, and vice versa. Nowhere is this more apparent than within the arena of wildlife law and regulation. Although collection and personal bait use of all salamanders not listed as endangered, threatened, or in need of management is permitted in the state, Tennessee law (TN WRCR 1660-1-17-.01B) allows for the sale (as bait) of only "dusky salamanders, *Desmognathus fuscus*" (Levell 1997). However, casual surveys of eastern Tennessee bait shops advertising "spring lizards" found at least seven other salamander species being sold, including *Desmognathus quadramaculatus* (P. Wyatt, pers. comm.), which is further protected as a species "In Need of Management" (Levell 1997). Georgia law (O.C.G.A. 27-1-28) lists "spring lizards," as one of fourteen groups of nongame wildlife exempt from any type of protection. The Georgia Department of Natural Resources does not interpret this portion of the law as including true lizards (Sauria) or salamanders other than *Desmognathus* spp., however the absence of a "spring lizard" definition may create a legal loophole providing little enforcement power for the protection of true lizards or non-desmognathine salamander species. Only those salamander species state-listed as endangered, threatened, or rare (*Ambystoma cingulatum, Amphiuma pholeter, Aneides aeneus, Cryptobranchus alleganiensis, Haideotriton wallacei, Notophthalmus perstriatus,* and *Plethodon petraeus*) are ensured legal protection. No species of lizards are currently listed as endangered, threatened, or rare.

In an effort to determine which species of salamanders are typically sold as bait in Georgia, and therefore provide a better definition of what should be considered legally commercialized species of bait salamanders, spring lizard bait boxes of nine shops in the north Georgia mountains (including Fannin, Forsyth, Habersham, Hall, Rabun, Towns, and Whitfield counties) were inventoried. Further, bait dealers were casually interviewed on various aspects of the spring lizard industry to gain a better understanding of its potential impacts. Visits were made on 29 May 1997 and 9 April 1998. Every salamander in each bait box was systematically identified and enumerated. Individual salamanders of uncertain species were purchased and mailed alive to qualified biologists for accurate identification.

Two species, *Desmognathus monticola* and *D. quadramaculatus*, accounted for more than 95% of all salamanders inventoried, though a total of seven species was encountered (Table 1). Bait dealers and fishermen recognize *D. monticola* and *D. quadramaculatus* as different species, referring to them as "light bellies" and "black bellies," respectively. Many fishermen prefer *D. monticola* over *D. quadramaculatus,* reporting them to be more active on the hook and to live longer.

Of the three other species of dusky salamanders encountered, *D. santeetlah* is of greatest interest. Presently, this species is known to occur only in North Carolina and Tennessee. Its discovery at a Georgia bait shop suggests that either the species ranges further south than currently known, or more likely, spring lizard collectors travel greater distances to sell their catch than would be expected. If indeed the *D. santeetlah* specimen came from within its known range, it was quite possibly collected illegally as the vast majority of its range falls within the Great Smoky Mountains National Park and adjacent National Forest lands.

Only two species of non-desmognathine salamanders, *Pseudotriton ruber* and *Gyrinophilus porphyriticus,* were found. These two species are marketed as "red dogs," and apparently are highly sought after by fishermen. Though not found during this survey, larval *Ambystoma tigrinum* are occasionally available at Georgia bait shops, where they are marketed as "mud puppies" or "waterdogs" rather than spring lizards (J. Ozier, pers. comm.). Non-desmognathine salamanders found in Tennessee bait shops included *G. porphyriticus, Notophthalmus viridescens, Plethodon serratus, Pseudotriton montanus,* and *P. ruber* (P. Wyatt, pers. comm.).

TABLE 1. Number of salamanders, by species, encountered at nine bait shops in northern Georgia, 29 May 1997 and 9 April 1998.

Species	Total no. of individuals	Percentage
Desmognathus fuscus	25	2%
D. monticola	686	67%
D. cf. *ochrophaeus*	1	<1%
D. quadramaculatus	310	30%
D. santeetlah	1	<1%
Gyrinophilus porphyriticus	1	<1%
Pseudotriton ruber	2	<1%

The sale of spring lizards is very seasonal, with most dealers offering them only during early spring and, occasionally, late fall. Spring lizards are mainly used to catch various species of bass, primarily from large reservoirs and other impoundments. Once late spring arrives and water temperatures begin to warm in these lentic bodies, spring lizards reportedly do not live long enough on the hook to be of much fishing value. During winter, collectors are not successful at finding enough spring lizards to continue pursuit and sale of them.

Most bait dealers sell spring lizards for US $4–$6/dozen after purchasing them for around US $2/dozen from individual collectors. "Red dogs" are usually sold individually and often are more expensive. One bait shop owner informed us that he typically buys four or five dozen spring lizards at a time and may purchase up to 120 dozen each year. In some areas of south and central Georgia, fishermen have north Georgia bait dealers or collectors send shipments of live spring lizards (E. Williams, pers. comm.). The presence of isolated colonies of *D. quadramaculatus* in south and central Georgia may be a result of the release of specimens distributed in this manner (Conant 1975).

There are several collecting methods employed, one of which is particularly disturbing. This method involves pouring liquid bleach into small streams, which apparently "shocks" the salamanders out from hiding. Collectors then easily grab up all the stunned animals and quickly wash them off. Obviously, this method likely creates a significantly negative impact on all the aquatic fauna and flora found in the streams where it is used. This method may impact populations of rare species, such as *Cryptobranchus alleganiensis* and several species of fish. Encouragingly, most bait dealers are very much opposed to this since spring lizards collected in this manner rarely live more than a couple of days. Several dealers informed us that one can occasionally smell the bleach on the spring lizards and that they often have "foggy" eyes. Individuals who collect spring lizards in this fashion will likely be "weaned-out" of this industry since dealers will not give them follow-up business. However, individuals who collect their own bait for a day of fishing may continue employing this method because it is fast, effective, and the animals should live, at least, through the day.

Another method practiced by some individuals involves stream diversion (M. Harris, pers. comm.). Small streams that run under unpaved roads can be diverted by placing a plywood board in front of the culvert, which backs up the water upstream from the road crossing. Once the water rises to the road level, ideally it then begins flowing down the tire-ruts of the road and away from the stream channel. Downstream from the culvert, the stream-bed is then exposed making it much easier to collect salamanders from under rocks. Others simply collect spring lizards by rolling rocks and logs in or adjacent to small streams and seeps, without the aid of stream diversion. Though none of the dealers we spoke with mentioned other collecting techniques, Camp and Lovell (1989) reported the use of a "fishing pole" equipped with an earthworm-baited hook for effectively capturing *D. quadramaculatus*. All methods reported involve collecting in or immediately adjacent to small streams, which may account for the encounter of only one *D.* cf. *ochrophaeus*. This species is noted for being more terrestrial and often living considerably further from water than most other *Desmognathus* spp. (Bishop 1943).

There are almost certainly additional species of salamanders that turn up from time to time in Georgia bait shops and additional collecting techniques are surely practiced. However, this study should provide the framework for applying more scientifically-based knowledge to laws and regulations involving bait salamanders in Georgia.

Acknowledgments.—Floyd Scott and Stephen Tilley confirmed the identity of several individual salamanders that puzzled us. We especially want to thank the owners and personnel at Crestview Grocery, Shady Rest Bait Shop, Field Stone Marina, Lakewood Bait and Tackle, Grant's Sporting Goods, Wahoo Trading Post, Hammonds Bait Shop, Wee Willy's No. 4, Wren's Bait and Tackle, and Freddy's Quick Service for their assistance with this inventory. Law enforcement officers with the GDNR provided information on bait shops that sold "spring lizards." The manuscript was improved through editorial comments provided by Mike Harris and E. J. Williams.

As an oceanic archipelago isolated from continental source areas, Hawaii lacks native terrestrial reptiles and amphibians. Polynesians apparently introduced seven gecko and skink species after discovering the islands approximately 1500 years ago, and another 15 reptiles and five frogs have been introduced in the last century and a half (McKeown 1996). The Polynesian introductions are probably inadvertent because the species involved are known stowaway dispersers (Gibbons 1985; Dye and Steadman 1990). In contrast, most of the herpetological introductions since European contact with Hawaii have been intentional. Several frog species were released for biocontrol of insects (e.g., *Dendrobates auratus*, *Bufo marinus*, *Rana rugosa*, Bryan 1932; Oliver and Shaw 1953), and most of the remaining species are released or escaped pets (e.g., *Phelsuma* spp., *Chamaeleo jacksonii*, *Iguana iguana*, McKeown 1996). Government-approved releases have not occurred for many years, but the rate of establishment of new species has increased in the past few decades because of the importation and subsequent release of pets.

We report the recent establishment in Hawaii of three new species of frogs native to the Caribbean: *Eleutherodactylus coqui*, *E. martinicensis*, and *E. planirostris*. Several Antillean *Eleutherodactylus* species have been introduced outside their natural ranges (Table 1) by hitchhiking with nursery plants, but these represent the first reports of establishment of the genus outside the general Caribbean region. *Eleutherodactylus coqui* recently

has been reported from Hawaii in the hobbyist literature (R. Campbell 1996; McKeown 1998), but either vouchered specimens were not provided and identification was unconfirmed (R. Campbell 1996) or claims as to identity and distribution included inaccuracies because they were based on erroneous assumptions and second-hand information from newspaper articles (McKeown 1998). McKeown (1998) did provide one vouchered specimen of *E. coqui* (USNM 515162, identified by R. Crombie, unexamined by us), although the locality data he provided are vague (USNM database records, R. Crombie, pers. comm.). We provide accurate locations for *Eleutherodactylus* species currently known to be introduced to Hawaii and, to the extent possible, information on the methods and rate of spread of these species, their habitat associations in Hawaii, their potential environmental impact in the state, and alternatives for management.

Eleutherodactylus coqui is documented with voucher material from three locations on Maui and five locations on Hawaii Is. (Fig. 1). One Hawaii Is. site and one Maui site are outdoor commercial plant nurseries. One Maui site is a resort hotel with grounds that are planted with horticultural species obtained from nearby nurseries. Two sites on Hawaii Is. and one on Maui are located in residential areas, at least one of which has considerable plantings of nursery material. The last two sites, both on Hawaii Is., are located in ornamental vegetation in a public park and in native forest, respectively. Frogs in the latter site probably originated from ornamental plantings at a nearby residence. The known elevational range of this species in Hawaii is 40–430 m. Populations seem to vary from a few calling individuals at the resort to several thousand individuals at the nursery on Hawaii Island, but all populations appear to be established and expanding, based on discussions with landowners or nearby residents. Population estimates at the Hawaii Is. nursery were based on collecting 105 frogs from an approximately $50m^2$ area in 50 minutes of casual nighttime collecting during very dry conditions lacking calling frogs, and extrapolating across the acreage known to have calling frogs. Virtually all of these captured frogs were adults. This density is approximately ten times that reported for *E. coqui* in unmanipulated native rainforest in Puerto Rico (Turner and Gist 1970, referenced as "*E. portoricensis*"; Stewart and Pough 1983). Although these frogs probably do not occur at this density uniformly throughout the nursery, it illustrates the large numbers and densities that have built up over the relatively short period of time (ca. 5 years) since the first calling frog was noticed.

Eleutherodactylus martinicensis is documented with preserved material from both a nursery at Kokomo, Maui (430 m elev.), which also has *E. coqui* (Fig. 1), and from a residence in Omaopio (~670 m elev.). The former apparently is an established population; the latter may only represent a translocation of a few calling individuals. The numbers of frogs at the nursery was not assessed because the call of this species is readily masked by syntopic calling *E. coqui*.

Eleutherodactylus planirostris is documented from three sites on Hawaii Is., all of which are at or adjacent to commercial plant nurseries, and one residential site on Oahu (Fig. 1). All are established populations. Elevations of sites are low, ranging from 60–190 m. In Jamaica, where this species also has invaded, it can occur up to 610 m elevation (Schwartz and Fowler 1973). Due to this species' cryptic habits and weak call, we did not estimate population sizes at any of the locations, but we routinely collected scores of individuals at night by walking the roadside grass margins at the Pahoa site. This site is adjacent to extensive ohia forests on 'a'a lava, suggesting that frogs also may occur in the native forest, as they do elsewhere where the species has invaded (Goin 1947; FK, pers. obs.).

Maui has the greatest number of reported locations with *Eleutherodactylus*. Radio public service announcements broadcasting the call of *E. coqui* and asking the public to report encounters with these animals have been playing on Maui since May 1998. This has resulted in our receiving additional reports of calling frogs from Honokowai, Ka'anapali, Kula, Ulumalua, Wailea, and Wailuku (Fig. 1). These are probably *E. coqui*, *E. martinicensis*, or mixed choruses of the two, given that they are the only two species known from the island, their calls are similar, and most reports have been in response to the broadcast calls. Most unverified sites are at resort hotels or from residential areas. Hotels from which frogs are reported are near sea level on the dry, leeward side of Maui. However, each is thickly planted with horticultural material and watered frequently, apparently providing sufficient moisture for frogs to thrive.

The route of entry of these frogs into Hawaii clearly appears associated with horticultural trade. The largest known populations of *Eleutherodactylus* in the State are found at active nurseries and their immediate surroundings. This is not surprising, given the propensity of each of these species to travel in greenhouse materials (Barbour 1930; Goin 1944; Gorzula 1989; Günther 1895; Lescure and Marty 1996) and the direct developmental mode of each. Although it is possible that each species has invaded the State more than once, we have no way to test this. Most populations appear to be the result of intra-state transport of frogs from infected nurseries to residential or resort sites landscaped with nursery materials. In at least two instances, calling frogs appeared after the purchase and installment of bromeliads for landscaping purposes. In one instance, bromeliads obtained from the Maui nursery with a large population of *E. coqui* and *E. martinicensis* were planted on 19 December 1996, and the first calling frogs (*E. coqui* only) at that residence were heard on 4 January 1997. However, we doubt bromeliads always are involved as vectors in the transport of these frogs. At the nurseries we have visited, *E. coqui* is common on palms, bamboo, *Dracaena*, and among unused pots and pallets. The nurseries around which *E. planirostris* is abundant specialize in raising *Dracaena*.

A second means by which *Eleutherodactylus* frogs may have dispersed in Hawaii is by intentional transport to establish new populations. In at least one case, a nursery owner with a conspicuous population of calling frogs allowed individuals inter-

[1] Not Kaiser (1992), as erroneously cited by Kaiser and Hardy (1994).
[2] Described by Kenny (1980) as *E. martinicensis*; referred to by Kaiser and Hardy (1994) and Kaiser and Wagenseil (1995) as *E. johnstonei*.
[3] Not *E. johnstonei*, as apparently erroneously cited by Kaiser and Hardy (1994) and Kaiser and Wagenseil (1995).

ested in establishing frogs at their residences to capture frogs from his property. We have been unable to confirm whether these intentional introductions have been successful, but the apparent ease of accidental establishment suggests this could be a viable route of range expansion for the frogs.

Of the three species discussed here, only *E. coqui* has been well-studied in its native range. It lays 4–6 clutches/yr, each with 16–41(mean = 28) eggs/clutch (Townsend and Stewart 1994). Generation time is approximately eight months (deduced from information provided in Townsend et al. 1984; Townsend and Stewart 1994; Turner and Gist 1970). We have received anecdotal reports indicating that population expansion of *E. coqui* at two sites has been rapid and in accordance with expectations based on this prior ecological knowledge. The owners of the large Hawaii Is.nursery reported to us that they initially had a single calling frog in 1992 or 1993, that there were several more calling the next year, and hundreds calling after two years. This is the earliest record of invasion that we have been able to discover so far. As noted above, our estimate is that many thousands of frogs are now calling from several acres at this site. In the instance of the bromeliad shipment noted earlier, landowners heard a single calling frog on 4 January 1997. They then left the State for six months. Upon their return in September, 1997, a few dozen individuals were calling around their residence. Approximately 25–30 calling males were removed from this site between 7 November and 6 December, 1997. These examples illustrate the short time required for *E. coqui* to expand in numbers from a small inoculum of individuals.

Most alien *Eleutherodactylus* species have become introduced to regions relatively near their native ranges that already contained a native frog fauna (Table 1) and, hence, these introductions have not introduced novel ecological challenges to the native fauna. The situation in Hawaii is different because of the original absence of reptiles and amphibians, and leads to concern about the ecological ramifications of introducing these animals to Hawaii or other herpetologically depauperate islands of the Pacific Ocean.

Of primary concern is that the elevational range tolerated by *E. coqui* (Schwartz and Henderson 1991) may allow it to invade native rainforest and mesic forest in Hawaii. In their native Puerto Rico, *E. coqui* can occur at densities greater than 20,000 animals/ha and crop an average of 114,000 prey/night/ha (Stewart 1995; Stewart and Pough 1983). We have seen no reason to expect lesser densities in Hawaiian settings and have evidence that they can match or exceed this. Should *E. coqui* invade native forest, consequent effects on native communities may be substantial: 1) they may exert a tremendous predation pressure on a wide array of native arthropods, primarily insects and spiders, many of which are already stressed to the edge of extinction due to the establishment of other alien predators and parasitoids (Cole et al. 1992; Gagné and Howarth 1985; Gillespie and Reimer 1993; Howarth 1985, 1990); 2) from this, one may expect a resulting indirect negative effect on native forest birds, the majority of which are partially or completely insectivorous (Munro 1944; Perkins 1903; Scott et al. 1986); 3) this rending of the native food web may result in the frogs serving as nutrient sinks (cf. Burton and Likens 1975) in the communities into which they insert themselves or, more likely, serving to enhance already large populations of introduced predators, such as rats and mongooses, which in turn will further increase predation pressure on native birds, a dynamic documented for alien predators elsewhere (E. Campbell 1996; Rodda et al. 1997) and suspected to occur for other taxa in Hawaii (Howarth 1985; Tomich 1986, p. 95). *E. martinicensis* may have a similar effect because its ecology seems similar in most respects to that of *E. coqui*. *Eleutherodactylus planirostris* should have less effect in this regard because it: 1) is currently restricted to relatively low elevations, which retain fewer native arthropods; 2) forages in leaf litter and on the ground surface instead of in tree canopies, reducing potential competition with birds; and 3) will probably not occur at most elevations dominated by native insects or birds.

From a more anthropocentric viewpoint, *E. coqui* and *E. martinicensis* are becoming nuisance species because of their loud calls and ability to live in the horticultural plantings around human dwellings. Several reports from Maui have come to our attention as complaints from residents whose sleep is disturbed by calling frogs. This has been a consequence of *Eleutherodactylus* introductions elsewhere as well (Lescure and Marty 1996; Pope 1917). Complaints from visitors at Maui hotels also have been lodged with resort managers, and at least one hotel has consulted with a pest control professional. In another instance, residents have vowed to move from Hawaii if the calling frogs on their property could not be eliminated. We expect these complaints to increase with time, unless introductions become actively managed. *E. planirostris* may be a lesser problem in this regard because of its less conspicuous call, although the one reported locality for this species on Oahu came to our attention because of dissatisfaction with the frogs' noise. A preliminary effort to investigate whether *E. coqui* transports plant nematode eggs on their skins has met with inconclusive results, but this ability would have potentially important consequences for nursery owners.

Most, and possibly all, populations of *E. coqui* and *E. martinicensis* are susceptible to eradication because numbers are still low at most sites and because males can readily be targeted for removal, thereby halting reproduction. Hand-capture, however, is inefficient, and efforts will soon be made to begin registration with the U.S. Environmental Protection Agency of a weak detergent solution for localized use in killing frogs. However, such efforts will be pointless until such time as relevant State officials actively pursue a program to ensure nursery material imported into Hawaii or offered for sale in-state is free of frogs or their eggs. This is difficult because of the magnitude of the ornamental plant trade in Hawaii, but can probably be achieved when nursery owners understand the potential problems the frogs may create for them. Public education of the threats posed by these frogs is ongoing in the form of public service announcements, fact sheets, and public talks, but is currently insufficient to meet the need for outreach to nursery owners, hotel managers, and agricultural officials, whose active support is necessary to control these frogs in Hawaii.

Acknowledgments.—We thank R. Bartlett, P. Bily, R. Crombie, F. Duvall, B. Farm, and E. Nishibayashi for assistance in collecting frogs, R. Crombie and J. Lynch for providing identifications of the species, and M. Fall and A. Koehler for providing comments on the manuscript.

Specimens Examined—*E. coqui*: HI: Hawaii Is.: NE of Huina Rd., Kurtistown (USNM 518648–64); Ka'iulani St., Hilo (BPBM 13296–97); Nahoa Rd., Leilani Estates, Puna District (BPBM 13751–52); Lava Tree State Park (BPBM 13753–54; Holualoa (BPBM 13750); Maui: Kapalua Bay Hotel, Kapalua (BPBM 13457); Kokomo Rd., Kokomo (BPBM 13459); Huelo (BPBM 13460). *E. martinicensis*: HI: Maui: Pea Place, Oma'opio (BPBM 13291); Kokomo Rd., Kokomo (BPBM 13292–95). *E. planirostris*: HI: Hawaii Is.: Auina Rd., Pahoa (USNM 518665–703, 518707–20, BPBM 13298–319); Kealakai St., Pana'ewa (USNM 518704–06, BPBM 13355); Oahu: Kaimalolo Rd., Waiahole (BPBM 13724–13729).

Unvouchered Records—*Eleutherodactylus* sp. (either *E. coqui* or *E. martinicensis*). Between 1 June 1996 and 21 June 1996, reptiles and amphibians were collected at La Selva Biological Research Station in Heredia Province, Costa Rica. Fecal samples were obtained and analyzed to document naturally occurring enteric parasite infections. Due to time and funding constraints, parasites were only identified to the generic level. Ninety-three animals were collected during the 126 h collection period (mean = 6 h per 24 h period).

All animals were held for no more than 48 h. Fecal samples were collected either from the specimen holding enclosure or manually expressed from the rectum. Animals were then released within 100 m of the original capture site. Sixty-four fecal samples from 23 species of reptiles and 12 species of amphibians were obtained. Fecal samples were collected in flotation cups (Fecalyzer, Evsco Pharamaceuticals, Buena, New Jersey) and refrigerated (<10 h) until examination.

TABLE 1. Parasite infection rates determined by fecal examinations of 35 species of reptiles and amphibians from Costa Rica.

Species	No. examined	No. infected
Snakes		
Bothrops asper	2	1
Chironius grandisquamis	1	0
Dendrophidion percarinatum	1	1
Imantodes cenchoa	5	4
Imantodes inornatus	1	1
Lampropeltis triangulum	1	0
Leptodeira annulata	2	2
Leptophis depressirostris	1	1
Micrurus nigrocinctus	1	0
Porthidium nasutum	1	1
Sibon nebulata	1	1
Lizards		
Ameiva festiva	2	2
Lepidoblepharis xanthostigma	1	1
Norops biporcatus	1	1
Norops capito	1	1
Norops carpenteri	3	3
Norops humilis	7	6
Norops lemurinus	4	4
Norops limifrons	1	1
Norops oxylophus	1	1
Norops pentaprion	1	1
Turtles		
Kinosternon leucostomum	1	1
Rhinoclemmys annulata	1	1
Total for Reptiles	41	35 (85%)
Frogs		
Agalychnis calcarifer	1	1
Bufo haematiticus	1	1
Bufo melanochloris	1	1
Dendrobates pumilio	5	3
Eleutherodactylus bransfordii	4	4
Eleutherodactylus crassidigitus	2	2
Eleutherodactylus fitzingeri	1	1
Gastrophyrne pictiventris	1	1
Hyla ebraccata	1	0
Leptodactylus pentadactylus	3	2
Scinax elaeochroa	1	1
Smilisca baudinii	2	1
Total for Amphibians	23	18 (78%)

Semi-quantitative fecal analyses were performed using direct smear and flotation methods (Bowman 1995; McCurnin 1994). Direct smears were examined under saline and/or Dobell & O'Connor iodine solutions (Becton Dickinson and Company, Cockeysville, Maryland). Flotations were performed in zinc sulfate solution (Vetus/Burns Veterinary Supply, Rockville Center, New York). Using a binocular (10x) light microscope, parasites were identified and quantified under 100x and 400x magnifications.

TABLE 2. Positive fecal results for 20 species of reptiles and 11 species of amphibians. Levels of infection are based on the following densities, as determined by a low power field (LPF; magnification of 100x) examination: 1+ = 1–2 eggs/LPF; 2+ = 3–5 eggs/LPF; 3+ = 6–8 eggs/LPF; 4+ = >10 eggs/LPF. <1 denotes parasite loads of rare/few.

Enteric parasites were found in 85% of reptile and 78% of amphibian fecal samples (Table 1). Parasites found in reptile feces included trichomonads (34% of samples with parasites), strongyles (26%), and coccidia (74%) (Table 2). *Isospora* sp. coccidia (Bovee and Telford 1965; Reichenbach-Klinke and Elkans 1965) were found in 51%, while *Eimeria* sp. (Bovee and Telford 1965; Reichenbach-Klinke and Elkans 1965) were found in 26% of the total number of samples with parasites. The mean rate of infection (excluding infections of <1) in reptile samples was 2.02 (SD = ± 1.18). The most common enteric parasites in amphibian fecal samples were trichomonads (49%), strongyles (39%), *Isospora* sp. (28%), and *Strongyloides* (28%) (Table 2). The mean rate of infection (excluding infections <1) in amphibian samples was 1.46 (SD = ± 0.63). Concurrent enteric parasite infections were found in 49% of reptile fecals and 30% of amphibian samples (Table 3). Relative levels of infection were low.

TABLE 3. Concurrent parasitic infection rates in Costa Rican herpetofauna.

2	13	32
3	5	12
4	2	5
Total	20	49
Amphibians		
2	4	17
3	3	13
4	0	0
Total	7	30

Several factors are known to affect levels of parasite infection intensity (Aho 1990). Some data representing Central and South American reptile parasite levels in the wild are available (Chitwood 1938; Goldberg and Bursey 1992; Lainson 1968; Upton et al. 1989; Van Sluys et al. 1994, 1997). Comparisons of parasite levels between wild populations and captive groups have been documented with some species (Baker et al. 1996). However, no data were found to compare to enteric parasite levels in reptiles and amphibians recently imported from Costa Rica.

Amphibians have been proposed as bioindicators for various anthropogenic stresses on ecosystems (Cooke 1981; Dunson et al. 1992; Hall and Mulhearn 1984). Amphibians are likely to be more susceptible to pollutants and habitat alterations than other vertebrates due to complex life cycles that expose them to pollutants in both aquatic and terrestrial habitats, permeable eggs/gills/skin that exchange materials freely with their surroundings, and intimate contacts with polluted soils or sediments for long periods when estivating or overwintering (Dunson et al. 1992). Terrestrial salamanders are an abundant component of northeastern forest ecosystems, with their total biomass exceeding that of breeding birds and mammals (Burton and Likens 1975; Hairston 1987). Salamander physiological functions and water and cation levels in body tissues are affected by alterations in soil pH (Frisbie and Wyman 1995; Wyman and Hawksley-Lescault 1987) and soil moisture (Heatwole and Lim 1961). Salamanders occupy intermediate positions in forest trophic webs (Hairston 1987; Pough et al. 1987), and impacts on them could directly affect adjacent trophic levels. Their sensitivity to abiotic conditions, abundance in forests, and trophic position make salamanders a potentially effective bioindicator of anthropogenic stresses on terrestrial ecosystems.

An integral component in assessing human impacts on amphibians involves *in-situ* enclosures of animals in areas affected to varying degrees. A variety of aquatic enclosures exist for amphibian eggs and larvae (Harris and Bogart 1997; Sadinski and Dunson 1992), but there are few designs for terrestrial salamanders. Terrestrial enclosures for salamanders should ideally meet several criteria if they are to be used effectively in ecotoxicological studies. First, they should be inexpensive, easy to construct, easily installed, durable, and portable. These features enable multiple replicate enclosures to be transported to remote field sites. Second, an ideal enclosure design would be adaptable for use with many salamander species, having differing habitat and space requirements. Finally, the soils within the enclosure should mimic the ambient abiotic and biotic conditions of the study site, and provide the enclosed salamander with the microhabitats normally utilized by that species under natural conditions. In this paper, we review several enclosure designs for terrestrial salamanders from the literature, and present a new design that is inexpensive, portable, adaptable, and has proven to be useful in assessing the effects of anthropogenic soil alterations on terrestrial salamanders.

Several existing terrestrial salamander enclosure designs fail to meet all of the criteria listed above, and so would be inappropriate for ecotoxicological studies involving terrestrial salamanders. Pechmann (1995) enclosed salamanders in large (225 m^2) tracts of terrestrial habitat surrounded with aluminum drift fencing, and recaptured them as they migrated to a nearby pond to breed. Although this method is flexible in meeting the space and habitat requirements of different species, the fencing can be labor-intensive to install, limiting the number of replicate sites that could be utilized. Additionally, this design does not allow for easy recapture of the enclosed animals outside of the breeding season, making it unsuitable for studies examining the physiological reactions of individual salamanders to differing abiotic soil conditions. Wyman (1998) used 1.2 m x 2.5 m (3 m^2) enclosures composed of wooden frames covered with mesh screening to investigate the effects of salamander predation on soil invertebrates and leaf litter decomposition rates. As with Pechmann's (1995) design, the enclosed salamanders are afforded sufficient space within these enclosures, but their large size would make them difficult to transport to remote field sites. Frisbie and Wyman (1995) constructed enclosures for *Plethodon cinereus* by removing the bottoms of 5 gallon polyethylene buckets and then forcing the bucket approximately 15 cm into the soil. These enclosures are inexpensive, portable, and easily installed, but they provide little surface area (0.051 m^2) and limit the variety of microhabitats available to the enclosed salamander.

Our design, modified from Frisbie and Wyman's (1995), includes the advantages of greater area and microhabitat complexity within the enclosure. We use large plastic plant pots (38 cm diam) as enclosures, although this method could be used with any size container. The enclosures are constructed by removing the bottom of the container with a hacksaw or reciprocating saw, creating a tapering cylinder (38 cm pot: volume = 0.0282 m^3 and surface area = 0.1134 m^2). The enclosures are installed by first placing the inverted enclosure on the soil, and tracing its outline on the soil surface. All leaf litter within the inverted enclosure is collected and saved. The soil around the outline is then excavated to a depth of 25–30 cm with a shovel, the organic and mineral soils removed, and placed in separate containers. The enclosure is placed in the hole, tapered side down, until the lower edge of the top lip of the enclosure is flush with the soil surface. The soil layers (mineral and organic) are then backfilled inside and outside the enclosure to their corresponding levels in the surrounding soil. Next, a 25 mm diameter PVC pipe is hammered into the center of the soil within the enclosure at a 45° angle and then removed to create an artificial mammal burrow within the enclosure approximately 25 cm long. Many species of terrestrial salamanders, particularly in the genus *Ambystoma*, are frequently found in mammal burrows in the soil (Douglas and Monroe 1981; Madison 1997; Madison and Farrand 1998; Semlitsch 1981; Williams 1973), and some of these species do not actively burrow (Semlitsch 1983). The inclusion of an artificial burrow within the

enclosure allows the salamander access to the upper soil layers that they would normally occupy. After creating the artificial burrow, the leaf litter is replaced inside the enclosure. The enclosure is then left in the soil for a minimum of 14 days to allow time for the abiotic soil conditions within the enclosure to approximate those of the surrounding soil. An individual salamander can then be placed in the enclosure, and the enclosure covered with a 58 x 58 cm piece of 1 mm fiberglass mesh screening or plastic utility screening (if larger mesh sizes are desired), secured to the enclosure with a 91.5 cm (36 in.) bungee cord (Fig. 1). At the conclusion of the experiment, the salamander can be collected directly from the enclosure if it is in the leaf litter or in the artificial burrow, or the enclosure can be searched by hand if the salamander's location is not immediately apparent. If the soil is sufficiently moist, the entire enclosure can be lifted out of the soil and its contents dumped into a large container where it can be searched.

This enclosure was originally designed for use with salamanders in the genus *Ambystoma*, but it can be modified to meet the habitat and surface area requirements of any salamander species simply by changing the size of the container used to create the enclosure. *Ambystoma* salamander home range sizes show considerable intra- and inter-specific variation, ranging from a few dozen square centimeters to over 200 m^2 (Kleeberger and Werner 1983; Semlitsch 1981; Williams 1973). Further, some species spend a vast majority of their time in several considerably smaller "activity centers" within their home range, and so may require even less area than the home range sizes for that species would suggest (Semlitsch 1981). The flexibility of this enclosure design allows the user to balance surface area requirements with logistical constraints, and to include within the enclosure any microhabitats (simulated mammal burrows, leaf litter, decaying logs) utilized by the species being examined.

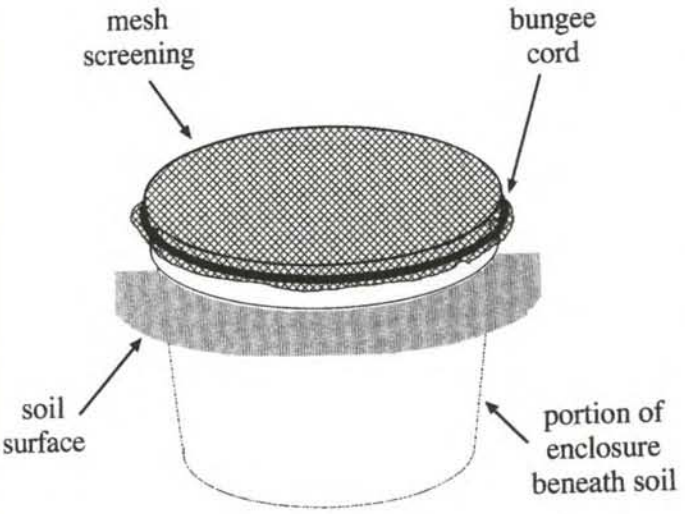

FIG. 1. Enclosure for terrestrial salamanders as installed in the soil.

We have used this enclosure design to examine the responses of juvenile *A. jeffersonianum* to soils altered by wastewater effluent irrigation, acidic deposition, and deforestation in central Pennsylvania, USA. In one study (Laposata and Dunson, in prep.), 40 juvenile *A. jeffersonianum* were individually enclosed for 28 days in clearcuts and adjacent forests in two regions in central Pennsylvania that received differing amounts of acidic atmospheric deposition. Abiotic soil conditions differed among the sites; sites in the region with higher deposition had lower soil pH than sites in the lower deposition region, and clearcuts had lower soil moisture levels than adjacent forests. Since the enclosure could prohibit soil invertebrates from entering the enclosure, the animals were fed red worms (*Lumbricus rubellus*) once weekly to insure that food was not limiting. At the conclusion of the experiment, salamander growth rates and body sodium concentrations were significantly lower in the region with higher deposition levels, and animals enclosed in clearcuts showed lower body water concentrations than those in forested sites. These results are consistent with laboratory studies in which salamanders were exposed to low pH substrates (Horne and Dunson 1994; Wyman and Hawksley-Lescault 1987) or low soil moisture levels (Heatwole and Lim 1961).

This enclosure method also was used to evaluate the impacts of the spray irrigation of treated wastewater effluent on *A. jeffersonianum* (Laposata 1998). Twenty salamanders were enclosed in irrigated and unirrigated areas for 35 days, and growth, body water concentration, and body concentrations of Na, K, Ca, and Mg compared in the two areas. No significant differences in any of the physiological parameters were detected in animals enclosed in irrigated and unirrigated areas, suggesting that wastewater effluent irrigation is not acutely toxic to terrestrial salamanders under natural conditions.

In both studies, soil temperature, moisture, and pH were compared inside the enclosure and at a randomly determined locations 1 m from the enclosure on the first (14 days after installation) and the last (28 or 35 days after the salamander was placed inside) day of each experiment to determine if soil conditions were altered within the enclosure. These soil conditions inside and outside the enclosures did not vary significantly at the start or conclusion of the experiment in either study, indicating salamanders within the enclosures were exposed to pH, moisture, and temperature levels like those in the surrounding soil (Laposata 1998; Laposata and Dunson, in prep.).

In these two studies, we enclosed a total of 60 salamanders in various habitats with greatly differing abiotic and biotic characteristics. Survival rates of the enclosed salamanders for each experiment were 100%, and three (5%) salamanders escaped from the enclosure or were unable to be located at the conclusion of the experiment. All three of the escapes were in forested sites with sandy soils, and the salamanders may have been able to burrow through the soil and escape through the open bottom of the enclosure. After these initial experiments, we modified our design to reduce the probability of escape. Prior to installation in the soil, we covered the bottom of the enclosure with a 58 x 58 cm piece of 1 mm fiberglass mesh screening, secured it with a bungee cord, and attached 4–5 large metal binder clips over the enclosure's bottom edge to hold the bungee cord in place. This modification caged the bottom of the enclosure as well as the top, and preliminary tests with this new design revealed no escapes of 20 enclosed animals over a 21 day period in the same soils in which the previous escapes occurred (Laposata and Dunson, unpubl. data).

The enclosures described in this paper are inexpensive (< US $5.00 each), simply constructed, easily installed, durable, and portable. Salamanders exposed to soils with differing abiotic conditions in these enclosures can experience measurable alterations in physiological parameters. This enclosure method could be used to evaluate a wide variety of natural and anthropogenic stresses on terrestrial salamanders, and facilitate their use as bioindicators of human impacts on terrestrial ecosystems.

Acknowledgments.—We thank Mike Libreatori for assistance in constructing the enclosures. Kendra Lentz and Chris Paradise provided helpful comments on early versions of the manuscript. Many thanks to G. L. Storm of the Pennsylvania Cooperative Fish and Wildlife Research Unit for arranging financial support from the Office of Physical Plant of The Pennsylvania State University, for a portion of the research described.

The Accuracy of Estimating Eggs in Anuran Egg Masses Using Weight or Volume Measurements

J. KIRWIN WERNER
JOSEPH WEASELHEAD

P.O. Box 117, Pablo, Montana 59855, USA
e-mail (JKW): jkw@ronan.net

To document amphibian mortality in early life history stages, it is important to know the number of eggs oviposited. Indirect methods such as weight or volume displacement have become more common (Corn and Livo 1989; Cuellar 1994) because counting all eggs in masses of hundreds to thousands is impractical. Weight or volume displacement should produce similar results with careful sampling. We tested this assumption using spring scales and volumetric flasks, and examined the error associated with these methods.

Egg masses were weighed in a half-gallon plastic bucket using an Ohaus 2000 g spring scale; samples were weighed in a 50 cc plastic vial with a wire handle using a Pesola 100 g spring scale. Egg mass volumes were measured in a 2500 cc flask with ~1000 cc of water and samples in a 50 cc graduated cylinder with ~10 cc of water.

Thirty egg masses of *Rana luteiventris* were taken from a series of ponds located on the Flathead Indian Reservation in western Montana, USA. Based on daily visits to the ponds, the eggs were 3–12 days old when analyzed. Although we made no attempt to stage the eggs, we categorized the mass as being Type I (N = 13 masses) if the matrix was relatively solid and the eggs small and circular or Type II (N = 17 masses) if the matrix was more soft and some eggs were beginning to elongate into the neurula stage.

After a mass was weighed and the volume determined, 10 samples of 10–40 eggs each were separated from the mass, counted, and the volume and weight recorded. The total number

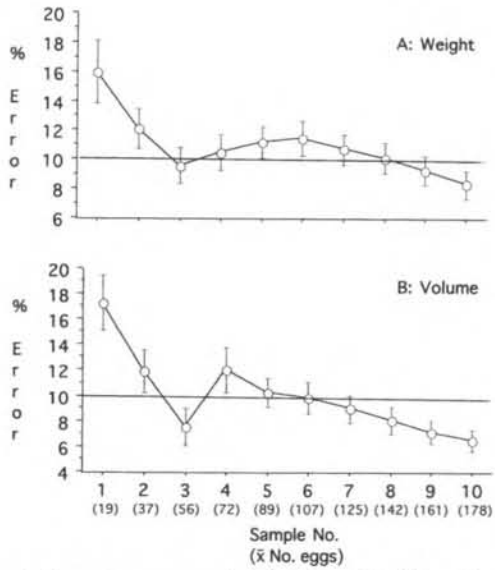

FIG. 1. Percent error associated with weight (A) and volume (B) estimates of egg mass number. Vertical lines represent one standard error. The horizontal line represents a 10% error. Number in parenthesis (x-axis label) is the mean number of eggs used in the sample; the mean number of eggs for all masses was 1035.

of eggs in the mass was determined by counting the remaining eggs.

For the first sample, the mean weight and volume of a single egg was estimated by dividing weight and volume of the sample by number of eggs in the sample. An estimate of the total number of eggs in the mass was made by dividing the total weight or volume of the mass by the mean weight or volume of an individual egg. The mean error was computed as: $E = (N_{estimated} - N_{counted}) / N_{estimated}$ (Corn and Livo 1984).

TABLE 1. Unpaired t-tests comparing weight vs. volume errors for samples 1, 3, and 10. T-tests are included for weight vs. weight and volume vs. volume errors for Type I and II egg masses.

Sample	Mean Diff.	DF	t-value	p-value
Weight vs. Volume Errors (N = 30 masses)				
1	0.013	58	0.43	0.67
3	0.005	58	0.29	0.77
10	-0.018	58	-0.43	0.16
Weight Errors: Type I vs. Type II masses				
1	0.066	28	1.54	0.13
3	0.030	28	1.24	0.22
10	0.003	28	0.01	0.99
Volume Errors: Type I vs. Type II masses				
1	0.021	28	0.47	0.64
3	0.023	28	0.85	0.40
10	0.025	28	1.62	0.12

In order to see how accuracy improved by increasing egg count, data from the first sample was combined with the second sample of 10–40 eggs and a new estimate was made. Data from the first and second samples were subsequently combined with a third sample and so on through 10 samples.

Egg count accuracy steadily improved through the first three samples (Fig. 1). Using absolute error values, regardless of whether they were over or under estimates, one sample of 10–40 eggs (1.8% of the mass) produced a mean error of 16% (range 1–37%); the error associated with volume determinations was 17% (range 2–42%). The mean error for both weight and volume dropped to 10% (range 0–28%) using three samples with a total of 41–80 eggs (5.4% of the mass). Further increases in sample size produced a slight increase in error and then a steady decrease (Fig. 1, e.g., range 0–17% using 10 samples). Errors below 10% were achieved with weight determinations in the 9th sample (161 eggs, range 137–230) and in the 6th sample (107 eggs, range 85–132) with volume determinations.

Mean errors for weight and volume estimations were not different at any sample size (Table 1). However, weight measurements consistently produced overestimates that were significantly different from a 1:1 over-under ratio (Table 2). Volume estimates approximated a 1:1 over-under ratio. Further, the mean errors for weight were different from zero in all samples whereas volume errors were not. Corn and Livo (1984) suggested that if the mean error was significantly different from zero, the estimate be adjusted by the mean error ($N_{adjusted} = (1 - E) \times N_{estimated}$).

Comparisons between Type I (early stage) and Type II (later stage) egg masses did not produce differences in either weight or volume errors (Table 1). Type II egg masses required more care in handling because of the sticky and loose nature of the mass.

TABLE 2. Chi-Square tests of over and under estimates for weight and volume determinations (samples 1, 3, and 10). T-tests for differences of the mean errors from zero.

	Sample	# Over Estimates	# Under Estimates	Chi-Square	Diff. from zero t-value
Weight	1	21	9	4.80[1]	4.16[2]
	3	23	7	8.53[1]	4.47[2]
	10	23	7	8.53[1]	5.13[2]
Volume	1	17	13	0.53	1.46
	3	13	17	0.53	-0.99
	10	14	16	0.13	-0.60

[1] = Significant at the $P < 0.05$ level or [2] = at the $P < 0.01$ level.

In summary, one sample of 10–40 eggs from a mass of approximately 1000 eggs produced substantial errors, in some instances as high as 42%. Increasing the sample size to 5% or more of the mass resulted in a mean error of about 10% (range 0–27%), which would seem acceptable for this type of equipment and field situation. Corn and Livo (1984) derived their data based on counting 5–10% of the mass. Although there were no significant differences between weight and volume estimates, the frequent overestimates observed with weight, and the fact that errors for weight determinations decreased slower than volume errors (Fig. 1), would suggest that volume determination was the better method. The overestimates with weight may reflect both the inaccuracy of the Ohaus scale and/or a tendency to add water to samples displaced in and out of a water medium. Trying to remove excess water by blotting egg masses is impractical, but a more accurate spring or digital scale would probably improve results. Although the age of the mass was not critical in the estimations, the older the mass, the more difficult it became to separate and count individual eggs. Because newly laid egg masses swell considerably in the first 24 h, the optimum time for making estimates is probably 2–5 days following egg laying.

A Technique for Sexing Red-Backed Salamanders (*Plethodon cinereus*)

VANESSA S. QUINN*

Red-backed salamanders (*Plethodon cinereus*) have been used as a model species for several investigations, including behavioral differences between males and females (Mathis et al. 1996). A difficulty in this regard is that techniques have not been established to determine sex using external characteristics for this species. The overlap in snout-vent length (SVL) ranges (e.g., males: 32–49 mm; females: 34–48 mm; Sayler 1966) demonstrates the inadequacy of a sexing technique based on SVL. Mental glands are sexually dimorphic during the mating season (fall and spring; pers. obs.). However, only sexually active males can be distinguished by the presence of enlarged glands, while females and sexually inactive males cannot be discriminated. In mature females, eggs may be visible in the abdomen, yet again, this technique is not adequate for distinguishing non-gravid females. Although these methods have been used to externally sex red-backed salamanders, no studies have been done to confirm their accuracy in this species, which requires internal investigation. In this paper we describe a new technique, confirmed via internal investigation, that may effectively allow for the external sexing of adults. We report a sexually dimorphic character, the distance between nares at the tip of the snout (inter-nares distance; IND), from Michigan populations.

In 1996, we collected 95 adult red-backed salamanders from Alger and Marquette counties, Michigan, USA. We preserved each individual in a 10% formalin solution and measured the distance between nares, at the tip of the snout, to the nearest 0.01 mm. We also measured SVL, to the nearest 0.01 mm, from the tip of the snout to the posterior portion of the vent using calipers. After measuring external characteristics, we dissected each individual. Adult males were sexed on the basis of pigmentation of the testes and vasa deferentia, while adult females were sexed on the basis of enlarged oviducts (Sayler 1966). Snout-vent length and IND of females and males were compared using t-tests. Both variables were first log-transformed to meet parametric assumptions. In 1998, we collected three adult males and three adult females from Clark Co., Illinois. Individuals from the Clark population were cooled on ice before measuring to determine if this technique would be of value in the field, as well as on preserved animals. These animals were not dissected, and therefore, not included in the data set.

From dissections, 55 males and 40 females were identified. The IND of males (mean = 0.27, SE = 0.04 mm) was significantly greater than the IND of females (mean = 0.19, SE = 0.05 mm; $T = 11.942$; $df = 93$; $P = 0.001$). The ranges of IND for males was 0.22–0.33 mm while, female IND ranges from 0.13–0.23 mm. Range overlap occurred among few animals (2 males and 2 females had IND = 0.22; 1 male, IND = 0.21; 1 female, IND = 0.23). Mean SVL did not differ between males and females ($T = 1.174$; $df = 93$; $P = 0.244$).

This report validates the use of IND as a sexing tool. In the field, cooling salamanders on ice allows the measurement of IND and SVL. Additionally, this is a tool that will allow the sexing of preserved specimens, without requiring dissection. Sexual dimorphism in this character has not been reported previously, thus, it is important to confirm the utility of this technique and the pattern of sexual dimorphism in other populations of *P. cinereus*, as well as other plethodontid salamanders. An understanding of patterns of sexual dimorphism in such characteristics in relation to ecological and taxonomic variation may shed light on the potential functional significance of sexually dimorphic characteristics.

Acknowledgments.—We thank D. K. Hews, P. A. Zollner, and two anonymous reviewers for helpful comments on an earlier version of this manuscript. J. F. Bombard assisted in collection and dissection.

Individual Identification of Captive Mexican Caecilians (*Dermophis mexicanus*)

KEVIN M. WRIGHT
and
TANYA MINOTT
Department of Herpetology, Philadelphia Zoological Garden
3400 West Girard Avenue, Philadelphia, Pennsylvania 19104, USA
e-mail (KMW): Kwright_pzg@compuserve.com

Most species of terrestrial caecilians lack obvious identification patterns making it difficult to distinguish individual animals. We have noted that the pattern of annuli (permanent skin folds sometimes called grooves or rings) is distinct for different individuals of *Dermophis mexicanus* held in captivity at the Philadelphia Zoo. Identification consists of noting which annuli are incomplete, broken, or bent. Photographs of the dorsal and ventral pattern can be made, but obtaining the photographs can be difficult and costly. An easy alternative to using photographs for identification is to obtain only the ventral pattern of the annuli by photocopying the caecilian while it lies in a transparent-bottomed container such as a clear plastic shoebox or a glass-bottomed aquarium. A light colored damp towel can be laid on top of the caecilian to reduce its movements during the photocopying and to provide a high-contrast background. A high-speed photocopier should be used to reduce the length of light exposure time required.

Although *Dermophis mexicanus* do have light-dark discrimination (M. Wake, pers. comm.), the risk of retinal injury from brief exposure to the photocopier's light is assumed to be minimal. The bright light and heat associated with photocopying may be distressing to some animals, especially if the light exposure exceeds 2–3 seconds, so we have restricted photocopy attempts to one or two per caecilian. No untoward effects of the photocopying process have been noted in any of the caecilians in the months to years following the procedure. The photocopy of the ventral pattern can then be analyzed for obvious characteristics

that are annotated to facilitate re-identification of the caecilian at a later date.

Although this method of identification has worked well for the small sample size (N = 17 as of 31 December 1997) of *Dermophis mexicanus* held at the Philadelphia Zoo, similar annular disjunctions may not be present in all specimens of a given population of this species (M. Wake, pers. comm.). In addition, the annular disjunctions may not be present in other species, especially those that lack secondary or tertiary annuli (M. Wake, pers. comm.). Other methods of identification, such as permanently implanted transponders, may be necessary to identify living specimens over long periods of time.

Effects of Marking *Uta stansburiana* (Sauria: Phrynosomatidae) with Xylene-based Paint

JAMES L. BOONE
and
ELIZABETH A. LARUE
Nevada State Museum
700 Twin Lakes Drive, Las Vegas, Nevada 89107, USA
e-mail: jlboone @ aol.com

Population biologists often rely on marks to identify individual animals (Nietfeld et al. 1994). For many years, herpetologists have marked reptiles with toe-clips, scale-clips, and paint (Ferner 1979), and although any marks potentially affect animals, generally these have been shown not to affect survival or other biological processes (e.g., Brown and Parker 1976; Jones and Ferguson 1980; Weatherhead et al. 1995). As technologies change, new methods of marking appear. Some new methods obviously require testing before one can be sure that the method does not adversely affect the target animal (e.g., glass beads, Fisher and Muth 1989; radioactive tags, Pendleton 1956; PIT tags, Prior and Weatherhead 1996).

One example of a new method entering use without being tested was a modification of standard painting techniques. Herpetologists have long used model paint (e.g., Testor Corporation paints) to mark lizards and snakes without adverse effects (e.g., Jones and Ferguson 1980). However, using model paint in the field can be messy and may require researchers to carry and use paint thinner, leading one to look for more convenient methods. Some researchers have used fingernail polish, while others have found quick-drying Faber-Castel™ paint-pens more convenient for marking reptiles than either model paint or fingernail polish. The carrier in these paint-pens, however, is xylene, and xylene has well-known toxic effects on animals (d'Azevedo et al. 1996; Rana and Kumar 1997). One might assume that marking a reptile with a small amount of paint would result in a negligible dose of xylene, especially in hot, arid environments where the paint dries almost immediately. Based on this assumption, one might conclude that using paint-pens would not affect lizard behavior, survival, or other demographic parameters. However, no one has tested this assumption.

We conducted a pilot study to test the null hypothesis that xylene-based paint-pens have no adverse effect on the survival of side-blotched lizards (*Uta stansburiana*), a small insectivorous lizard that is common in the western USA and northern Mexico. We captured 35 *U. stansburiana* (18 female; 17 male; 19 adults, snout–vent length, SVL > 39 mm; 16 juveniles, SVL ≤ 39 mm) from five locations around southern Nevada (October, 1996 through October, 1997). We held the lizards in a lab and housed them on sand and gravel in individual 2-liter jars. We exposed the lizards to ambient light and provided full-spectrum lamps for heat during daylight hours. Daily ambient temperatures in the lab ranged from about 13–27°C. Before marking the lizards, we kept them in captivity for 2–3 days to ensure that no animals died immediately after capture.

We painted 21 lizards and used 14 as unpainted controls. We painted lizards in a manner similar to how *U. stansburiana* had been marked during a previous mark-recapture study (Boone et al. 1998). We placed a spot of paint on the dorsum (diameter ≤ 1 cm, less than the width of the dorsal surface) generally every 3–4 days until each lizard had been painted four times. This simulated four capture-recapture events over two weeks using a different color of paint specific to each day of sampling. In the field, large spots (i.e., the width of the dorsum) were used so that the paint color could be seen from a distance. Each successive spot of paint was placed on top of the previous spots. We recorded mortality and sleeping behavior (i.e., spending the night above or below ground) for two weeks.

Of the 21 painted lizards, five died (four juveniles, one adult; 24%), all of which had been painted at least twice. No unpainted lizards died. While the sample size was small, the result was statistically significant ($G_{adj} = 5.408$, $P = 0.02$). Sleeping behavior also changed. When first brought into the lab, all lizards burrowed into the substrate and spent every night underground. During the remainder of the study, most unmarked lizards continued to burrow underground almost every night (Table 1). By contrast, 8 of 11 (73%; $P = 0.06$) painted juveniles, and 2 of 10 painted adults (20%; $P = 0.62$), switched sleeping location and spent almost every night aboveground (Table 1).

When first applied, the paint sometimes appeared to irritate the lizards: they sometimes gaped, some exhibited dorso-ventral flattening as if a weight had been placed on their back, and a few

TABLE 1. Frequency at which 35 *Uta stansburiana* from the southern Nevada region spent the night above or below ground after having been marked, or not-marked, with xylene-based paint-pens. Data were summarized for all lizards, for juveniles (SVL ≤ 39 mm), and for adults (SVL > 39 mm).

	All Lizards		Juvenile		Adult	
Sleeping Position	Marked	Not-marked	Marked	Not-marked	Marked	Not-marked
Above Ground	10	2	8	1	2	1
Below Ground	11	12	3	4	8	8

flexed their bodies 45–60° backwards lifting their front legs off the ground or pressing their front legs against the side of their jar. Some of the painted lizards became lethargic. There seemed to be a dose-response relationship. More smaller lizards than larger lizards showed negative responses to the paint, and the lizards that showed a negative response often did so after their second paint treatment.

Not all samples gave the same result. A group of five lizards (SVL = 42–47 mm) captured south of Las Vegas never exhibited any negative reactions (three marked, two unmarked). In contrast, from a group of nine lizards caught west of Las Vegas, four (SVL = 37–45 mm) of five painted lizards exhibited negative reactions, and the lizard that did not show a response (SVL = 52 mm) was the largest of these five.

The xylene-based paint used in this study was associated with the death of some lizards; it was also associated with altered behavior in others that could affect survival. If lizards in the field failed to seek cover at night, they may be subjected to increased predation or stressed by exposure to low temperatures.

Our observations suggest that *Uta stansburiana* experiences a dose-related, adverse effect from this marking technique. Although small amounts of paint may not affect these lizards, it appears that xylene-based paints can introduce unnecessary bias into field experiments, and therefore field biologists should avoid using these paints for marking lizards or other animals. An important point is to beware of new methods in the guise of old ones, and to carefully examine new techniques and procedures before assuming they are the same as the old favorites.

Acknowledgments.—We thank D. Beck, J. Freilich, A. Heindl, and G. Austin for helpful comments on the manuscript.

Benzocaine as "a convenient killing agent for amphibians" was first reported by Altig (1980) and then described by McDiarmid (1994). Altig placed a small dose of benzocaine-containing gel (e.g., Orajel® regular, 7.5% benzocaine) on a frog's head to kill it. Orajel® is a product that can be obtained easily at any pharmacy. We modified this technique by gently rubbing benzocaine (Orajel® regular, 7.5% benzocaine or Orajel® extra strength, 20% benzocaine) on the animal's ventral surface instead of its head. For anurans, benzocaine can be applied to the pelvic patch area rather than the entire venter. Benzocaine applied to the venter was absorbed faster than when applied to the head.

Hyla cinerea individuals were euthanized using both head and pelvic patch application methods. Individuals with pelvic patch applications died approximately 5–10 times faster than individuals with head applications. For anurans, the amount of Orajel® was proportional to body size: smaller species (less than or equal to 6 g wet weight) needed only a 10 mm diameter dollop (approximately 0.1 g) of gel, while larger species (greater than 6 g wet weight) needed a 25 mm diameter dollop (approximately 0.3 g) of gel. One salamander species (*Eurycea quadridigitata*) was also tested. Individuals required a 5 mm diameter dollop (approximately 0.05 g) of gel. We did not test Orajel® on caecilians.

Once benzocaine was applied, the animals were placed in a plastic bag. Individuals appeared completely relaxed and death occurred within 5 min for anurans and less than 1 min for *E. quadridigitata* (M. A. Donnelly, pers. comm.). Benzocaine gel application enabled individuals to be positioned easily as scientific specimens and only small amounts of skin toxins appeared to be released. A second application was necessary for a few individuals greater than 60 g wet weight (e.g., *Phyllomedusa bicolor, Bufo marinus, B.guttatus, Leptodactylus bolivianus, L. knudseni, L. rhodomystax,* and *L. mystaceus*). We were able to euthanize 50 individuals weighing 0.8–5 g using approximately one tube of Orajel® (7.08 g).

This methodology worked successfully for over 1500 individuals from both temperate and tropical anuran families including Hylidae, Microhylidae, Bufonidae, Leptodactylidae, Dendrobatidae, Centrolenidae, and Pipidae. Only one species (*Leptodactylus petersi*) consistently needed more than two applications of benzocaine for successful euthanasia. This was not a leptodactylid trait as other species in the family (*L. mytaceus, L. bolivianus, L. knudseni, L. rhodomystax, Ceratophrys cornata,* and *Adenomera andreae*) did not need more than two applications of Orajel®.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 29, Number 1 (March 1998).

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). **ALBINISIM**. Herein we report three partially albino *Ambystoma opacum* larvae. Two were discovered from the same vernal pool in Tiverton, Newport County, Rhode Island, USA (BD, JB) during 1988. A third specimen was found during March 1997 from a vernal pool in Lyme, Connecticut, USA (HG).

On 31 March 1988, an albino *A. opacum* larva (46 mm TL) was captured in 16.5 cm of water at 1535 h. The ambient temperature was 13.5°C; water temperature was 12°C. A second albino larva (50 mm TL) was captured on 6 May 1988 in 30.5 cm of water at 1200 h; ambient temperature and water temperature were 15.5°C and 14.5°C. This specimen was photographed at the capture site and released.

The coloration of both living animals appeared identical. Alive, the larval integuments were transparent with a yellowish cast; eyes appeared normally pigmented except that the pupils were pink, and the visceral organs, major blood vessels, and developing cranium were clearly visible through the integument. The external gills were flushed orange-red from blood. Preserved, the first larva appeared chalky-white with a slight hint of its former yellowish cast. This animal was catalogued in the American Museum of Natural History (AMNH 130240). Using definitions from Harris (1970. Bull. Maryland Herpetol. Soc. 6:21–22), both specimens were partial albinos, possessing integumentary xanthophores and orbital melanophores.

On 27 March 1997, another albino *A. opacum* larva was discovered in a vernal pool in Lyme, Connecticut. The coloration of this specimen was similar to that of the Tiverton larvae except the gills were yellowish and showed no red coloration from its blood, the eyes were slightly darker yellow than the integument, and most of the tail musculature was devoid of color and appeared white. The animal was placed in a jar, photographed, and returned to the pool. Color slides of this larva were sent to AMNH.

Albinism in *A. opacum* has been documented twice previously, once from Maryland (Harris, *op. cit.*) and once from Mississippi (Dyrkacz 1981. SSAR Herpetol. Circ. No. 11). To our knowledge, this is the first documentation of albinism for *A. opacum* in New England.

We thank Dr. Wang Yong and Charles W. Painter for their comments on this manuscript.

Submitted by **BOB DEEGAN**, 97 Raymond Street, Fairhaven, Massachusetts 02719, USA, **JOHN BERKHOLTZ**, Franklin Park Zoo, Children's Zoo, 1 Franklin Park Road, Boston, Massachusetts 02121, USA, and **HANK GOLET**, 5-1 Binney Road, Old Lyme, Connecticut 06371, USA.

GYRINOPHILUS PORPHYRITICUS (Spring Salamander). **COLORATION**. Although many *Gyrinophilus porphyriticus* spend much time underground, making use of subterranean springs and caves (Bishop 1947. Handbook of Salamanders. Comstock, Ithaca, New York. 535 pp), albinism has been reported in only one population (Brandon and Rutherford 1967. Am. Midl. Nat. 78:537–540; Dyrkacz 1981. SSAR Herp. Circ. 11). On 1 May 1997 in Chenango County, New York, USA, we found an albino (leucistic) larval *G. porphyriticus* (66 mm SVL, 50 mm TL) at the emergence of an underground spring ca. 550 m elev. The individual had a completely pigmentless integument, gills pink with hemoglobin, and normally pigmented eyes. A total of 15 larvae and adults, all normally pigmented, were found at the same site over a 15 day period. The specimen is deposited in the SUNY Cortland Bowers Natural History Museum (97-101PKD).

Submitted by **CARMEN FERRIERO**, **SCOTT MILLER**, **MATTHEW CHAPMAN**, and **PETER K. DUCEY**, Department of Biological Sciences, State University of New York at Cortland, Cortland, New York, 13045 USA.

PLETHODON HUBRICHTI (Peaks of Otter Salamander). **ALBINISM**. Albinistic and leucistic salamanders in the genus *Plethodon* have been recorded for *P. cinereus* (Harris 1968. Bull. Maryland Herpetol. Soc. 4:57–60; Pauley 1974. Redstart 41:104), *P. dorsalis* (Thurow 1955. Copeia 1955:62–63), *P. glutinosus* (Piatt 1931. Copeia 1931:29), and *P grobmani* (reported as *P. glutinosus*, Highton 1956. Copeia 1956:75–93).

On 26 May 1996, we found a leucistic, gravid, adult female *P. hubrichti* (53 mm SVL, 111 mm total length, 1.9 g) in the George Washington and Jefferson National Forest, 960 m, 7.0 km SE Arcadia (79°33'55", 37°29'38"), Botetourt County, Virginia, USA (Fig. 1). Integumentary pigment was completely lacking, although she had normally pigmented eyes. She was found in a six-year-old clearcut of striped maple (*Acer pennsylvanicum*) and red oak (*Quercus ruber*) saplings. We maintained the female in captivity to obtain reproductive data but despite efforts to induce feeding, she died about 10 weeks after capture. This is the first record of the leucistic phase of albinism in this endemic Blue Ridge Mountains species. The specimen is catalogued in the Virginia Museum of Natural History (VMNH 8086).

TARICHA TOROSA TOROSA (Coast Range Newt). **PREDATION**. On 20 July 1996 at the Santa Rosa Plateau Ecological Reserve, Riverside County, California, USA, we obtained a 194 mm SVL adult male bullfrog (*Rana catesbeiana*). Examination of its stomach contents revealed two predaceous water beetles (Dytiscidae) and a recently ingested, 76 mm SVL, adult male, *T. t. torosa*. The newt was deposited at the California Academy of Sciences (CAS 203181).

From 30 June–23 September 1997 at Ledson Marsh, Annadel State Park, Sonoma County, California, 3 adult and 2 larval *T. t. torosa* were flushed from the stomachs of an adult male and 3 adult female *R. catesbeiana* 183, 180, 141, and 122 mm SVL. In all cases, the skin of the adult newts had been digested. Other prey items included 3 subadult Pacific treefrogs (*Hyla regilla*) and one dragonfly nymph (Aeshnidae).

Bullfrogs have been poisoned by ingesting northern rough-skinned newts (*Taricha granulosa granulosa*) in Oregon under both experimental and wild conditions (Brodie 1968. Copeia 1968:307–313). These observations presumed that since bullfrogs were recently introduced into the American West and did not co-evolve with Pacific newts (*Taricha* spp.), they have not had sufficient time to develop any resistance to the potent toxins found in all life stages of *Taricha*. Our observations provide evidence that adult bullfrogs consume both larval and adult *T. t. torosa* in the wild, and naturalized bullfrogs may indeed have acquired some resistance to tetrodotoxin.

Our thanks to Robin Wills, Scott Principil, and Gary Bell for assistance in the field, and to Galen B. Rathbun and Norman J. Scott, Jr. for reviewing the manuscript. Permission to collect specimens was granted under California Department of Fish and Game permits issued to the authors. The Nature Conservancy allowed the use of facilities on the Santa Rosa Plateau Ecological Reserve.

Cotati Avenue, Rohnert Park, California 94928-3613, USA.

TARICHA TOROSA (California Newt). **PREDATION**. Members of the genus *Taricha* are known to contain toxic skin secretions and terrestrial forms have few predators (Stebbins and Cohen 1995. A Natural History of Amphibians. Princeton Univ. Press. Princeton, New Jersey. 316 pp).

On 15 July 1997 at 1500 h along a first order stream in the Santa Monica Mountains, Los Angeles County, California, USA, we found a ringneck snake (*Diadophis punctatus* 48 cm TL, 40 cm SVL) swallowing a *T. torosa* (7.8 cm TL, 3.8 cm SVL). The head and forelimbs of the newt were entirely consumed with only the hindlimbs and tail protruding. When we picked up the snake it was lethargic and did not attempt to move. We were unsure if the snake's behavior was defensive or a reaction to the newt toxins. The snake was collected and returned to the laboratory where it remained lethargic. The next morning (15 h later) the snake had regurgitated the newt. The snake's behavior appeared normal and the newt was dead. Based on these observations it is unclear if *T. torosa* are a regular part of the diet of *D. punctatus*. However, *D. punctatus* apparently attack *T. torosa* and a percentage of these attacks likely result in mortality for the newts either because of consumption or capture.

ANURA

HYLA AVIVOCA (Bird-voiced Treefrog). **AMPLEXUS and OVIPOSITION**. Compared to most other North American *Hyla*, little is known about the life history of *Hyla avivoca*, with most data collected from chorusing males. The non-vocal females are seldom observed, and previously reported observations on oviposition (Hellman 1953. Publ. Res. Div. Ross Allen's Rept. Inst. 1:61–74; Trauth and Robinette 1990. Bull. Chicago Herpetol. Soc. 25:218–219; Volpe et al. 1961. Copeia 1961:340–349) were of females of amplexing pairs collected in the wild that later oviposited in the lab or in collecting containers. Herein I report observations of amplexus and oviposition in two pairs of *H. avivoca* in nature.

The first observation took place on 24 May 1997 at Bell Pond, Johnson Co., Illinois, USA (T13S R4E SW/4 Sec. 11). Air temperature was 20°C with light but steady rain. At 2211 h a female was observed approaching a male calling on a limb of a pumpkin ash (*Fraxinus tomentosa*) ca. 1.7 m above water and 3 cm from the trunk. The tree was in clear water 8 cm deep. The female ascended the tree and when she reached the male (at 2215 h) she reached out with one hand and touched him on a hind limb. The male immediately turned toward her, climbed onto her, and clutched her in axillary amplexus. As the male was mounting and for several minutes afterwards, he emitted a call that sounded like the breeding call, but which had a more "raspy" sound (possibly because he was unable to fully inflate his vocal sac). The pair remained on the perch until 2227 h when they descended the tree head first. At 2235 h when the pair reached the water, the female paused and remained still until 2241 h then she turned and oriented so that her head faced up the tree with her cloaca ca. 1 cm above the water. She then backed into the water until the posterior third of her body and half of the male's body were submerged. Oviposition began immediately. The female arched her back and released one or both hind limbs from their grip on the tree trunk and appeared to close both eyes each time a cluster of eggs was laid. The first cluster of six eggs sank slowly to the substrate. Additional clusters of 3–9 eggs were laid at 1–4 min intervals over the next 40 min and I estimated 150–180 eggs were laid. Most sank slowly to the pond substrate of dead leaves and formed one mass, but at least three clusters adhered to the trunk of the tree between the water surface and substrate. This observation ended at 2324 h with the pair still amplexed and ovipositing.

The second observation began at 2110 h on 3 July 1997 at Reevesville Swamp, Pope Co., Illinois, USA (T13S R5E NW/4 Sec 31). A female was observed ascending the stem of a reed (*Phragmites* sp.) near another on which a male was calling ca. 1.3 m above the water. She paused when the male stopped calling

and rapidly climbed the reed she was on, or moved closer when the male resumed calling. By 2117 h the female had reached the base of the leaf where the male was perched. When she stepped onto the leaf the male oriented toward her, then climbed onto her (head first) and clasped her in axillary amplexus. The male continued to call (though the calls sounded more raspy than before) until 2123 h. The pair remained in place until 2132 h when the observation was interrupted. By 2140 h the female had descended to within 0.3 m of the water and climbed onto a low buttonbush (*Cephalanthus occidentalis*) branch in contact with the reeds where amplexus began. The female continued to descend the branch until she reached the water at 2147 h. She continued on the branch until her body (behind the shoulders) was submerged (only the posterior third of the male was submerged). The water was fairly clear, ca. 0.2 m deep over a substrate of mud, and covered by a thick mat of duckweed (mostly *Lemna* sp.) thus making oviposition difficult to observe. At 2153 h the female released her hind limb grip, thrust her head and cloaca upwards, and deposited an egg cluster. This behavior was repeated four times by 2205 h when I attempted to determine if eggs were sinking by gently scooping up or pushing duckweed from behind the frogs. One cluster of three eggs adhered to the *Cephalanthus* branch, but no others were seen. I ended the observation at ca. 2210 h. During subsequent visits on 6 and 10 July, three and seven *H. avivoca* tadpoles were collected from well shaded water in the interior of the same *Phragmites* thicket. Despite repeated attempts, no *H. avivoca* tadpoles were seen in an adjacent sunlit pond with scattered cattail (*Typhus* sp.) and *Cephalanthus* stands (where *H. cinerea* and *Acris crepitans* tadpoles were abundant), nor in a shaded cypress (*Taxodium distichum*)-tupelo (*Nyssa aquatica*) swamp where many male *H. avivoca* were heard calling previously.

I thank R.A. Brandon for reading a draft of this manuscript.

Submitted **by MICHAEL REDMER**, Department of Zoology, Southern Illinois University at Carbondale, Carbondale, Illinois 62901-6501, USA.

HYLA CHRYSOSCELIS (Gray Treefrog). **HIBERNACULA.** On 14 December 1996, ca. 15 km NE Fredericktown, Knox County, Ohio, USA, at a site composed predominantly of sugar maple (*Acer saccharum*), I unearthed a *Hyla chrysoscelis* from its apparent hibernaculum. This specimen was found 30.2 cm from the base of a sugar maple that was joined with another at its base. Both litter and soil were carefully raked out from the base of the tree in a circular fashion for one meter. Another *H. chrysoscelis* was discovered on the south side of the same tree 57 cm from the base. Leaf litter depth varied from 3.5–7 cm. The frogs were located 2.5 and 5.0 cm beneath the soil surface. Air temperature was ca. 4°C and the soil was not frozen. The leaf litter and soil around the base of eight additional trees were investigated in a similar manner and three more *H. chrysoscelis* were discovered. All were found in the soft, loose soil, but not in any of the numerous rodent tunnels at the bases of the trees. The total area examined was ca. 200 m^2.

In all cases the specimens were found in situations above the frostline. *Hyla chrysoscelis* is a freeze-tolerant species, known to survive temperatures less than 3°C and shows blood glucose concentration and dehydration levels that are similar to *H. versicolor* (Costanzo et al. 1992. Copeia 1992:565–569). Based upon this information it should not be surprising to find *H. chrysoscelis* during the winter months in shallow hibernacula as noted in this observation.

Submitted by **GARY BURKHOLDER**, Department of Biology, Mt. Vernon Nazarene College, Mt. Vernon, Ohio 43050, USA.

HYPEROLIUS TUBERILINGUIS (Tinker Reed Frog). **OVIPOSITION.** Nest building behavior in frogs appears to have evolved independently in at least five families: Rhacophoridae, Myobatrachidae, Leptodactylidae, Hylidae, and Hyperoliidae (Haddad et al. 1990. J. Herpetol. 24:225–226; Duellman and Trueb 1994. Biology of Amphibians, Johns Hopkins University Press, Baltimore, Maryland). Few reports describe the details of nest construction and few data exist on the breeding behavior of the largely African family Hyperoliidae. *Hyperolius tuberilinguis*, a widely distributed species throughout the eastern coastal plain from Kenya to KwaZulu-Natal, South Africa (Pallet and Passmore 1988. Bioacoustics 1:13–23), deposits its eggs in a nest constructed of egg jelly attached to emergent vegetation. Rose (1962. The Reptiles and Amphibians of Southern Africa, Maskew Miller, Cape Town) described the nest as "a mass of very sticky, crystal clear jelly attached to the stalks (of plants) about five inches above the water." Wager (1986. Frogs of South Africa. Delta Books, Craighall) and Poynton and Broadley (1987. Ann. Natal Mus. 28[1]:161–229) make similar observations but add that the size of the nest is ca. 35 x 50 mm. The process of oviposition and nest construction has not been observed (Passmore and Carruthers 1995. South African Frogs: a Complete Guide, Witwatersrand University Press / Southern Books, Johannesurg). Herein we report on the behavior associated with oviposition and nest construction in *H. tuberilinguis*.

On 10 February 1997, four amplexing pairs of *H. tuberilinguis* were observed at Wits Pond, Twinstreams Farm, Mtunzini, KwaZulu/Natal (28°51'S; 31°46'E), South Africa, between 2200 h and 0300 h. The first pair formed at ca. 2220 h, the second and third at ca. 2330 h. The fourth pair was not observed forming. Oviposition and nest construction were observed in two of these pairs. The first pair initiated oviposition by 2300 h on a leaf of *Hibiscus diversifolius* 210 mm above the water. The second pair deposited an egg mass at the base of an emergent *Typha capensis* 20 mm above the water.

Oviposition involved the pair positioning themselves heads up on the leaf. The female grasped the edges of the leaf with both fore- and hind-limbs. Males did not help with the grasping of the leaf. An initial egg mass was laid with only the male appearing to push the eggs against the leaf with his hind-limbs. Oviposition took 25 min. for the first pair and 23 min. for the second, with egg masses measuring 37 x 31 mm and 44 x 39 mm.

Both pairs left the egg masses when oviposition was complete and returned ca. 6–7 m to the water. One pair remained half-submerged in the water for 50 min, the second pair remained half-submerged for 65 min. Both pairs then returned to the previously laid egg masses. During this entire period the male and female remained in amplexus. Upon reaching the egg mass the pairs proceeded to deposit more egg jelly on the egg mass after a delay of three minutes for the first pair and two minutes for the second. The process of adding egg jelly lasted for 30–40 min. in both pairs. During this time no more eggs were deposited. Both the male and female spread the jelly over the egg mass using their hind-limbs. Only the female appeared to contribute to the production of the jelly. This procedure, of returning to the water and then to the egg mass to deposit more egg jelly, occurred twice in both pairs. The elapsed time from commencement of egg laying until completion of the nest was 190 min. for the first pair and 210 min. for the second. The completed egg masses measured 59

x 55 and 58 x 50 mm. The added egg jelly was clear and extremely viscous. It remained moist until the nest's degeneration, ca. 3 days later, and the subsequent emergence of the tadpoles. The construction of nests by *H. tuberilinguis* appears to be unique in this family. We know of no other published accounts of nest construction for members of the Hyperoliidae, specifically *Hyperolius*.

We thank the Foundation for Research Development for funding and Mondi Forests, South Africa for permission to work on their property.

RANA CASCADAE (Cascades Frog). **PREDATION.** *Rana cascadae* is nearly extinct at its southernmost limit—Lassen Volcanic National Park and vicinity, northern California, USA (Fellers and Drost 1993. Biol. Conser. 65:177–181). About 150 km NW of the Lassen area, *R. cascadae* persists at some sites in the Shasta area (pers. obs.; Fellers and Drost, *op. cit.*). One of many hypotheses why amphibians have declined is that novel (non-native) predators harm populations through evolutionarily unprecedented predation (Hayes and Jennings 1986. J. Herpetol. 20:490–509). But little direct evidence exists documenting the presumed predation. Here I present an observation of *R. cascadae* predation that supports the novel predator hypothesis.

On 17 October 1992 I observed an adult *R. cascadae* (ca. 50 mm SVL) jump into Butte Creek at ca. 1765 m elevation on the northeast slope of Mount Shasta volcano. The frog remained motionless on the creek bottom for several seconds, but was seized and eaten by a brown trout (*Salmo trutta*; ca. 200 mm fork length [FL]) as the frog began to swim downstream.

This observation confirms that *S. trutta* will eat *R. cascadae* under natural conditions, and that fish predation threatens adult frogs as well as (presumably) tadpoles (Bradford 1989. Copeia 1989:775–778). Fish do not always decimate *R. cascadae* populations, however, as a simple predation hypothesis might suggest (see Jennings 1996. Status of Amphibians, Sierra Nevada Ecosystem Project: Final Report to Congress, Centers for Water and Wildland Resources, University of California, Davis). A reproductive population of *R. cascadae* persists at Gumboot Lake west of Mt. Shasta City despite the presence of a trout fishery at the lake (pers. obs.; Fellers and Drost, *op. cit.*). For more than 25 years, California Department of Fish and Game has repeatedly stocked ca. 180 mm FL rainbow trout (*Oncorhynchus mykiss*) and brook trout (*Salvelinus fontinalis*) into the lake for sport fishing.

I thank Matt Simons, Brad Shaffer, Michael Rode, and Mark Jennings for assistance. Research was funded in part by The California Nature Conservancy and University of California at Davis.

Submitted by **LEE H. SIMONS**. Shasta Natural History Foundation, 913 Shasta Avenue, Yreka, California 96097-3115, USA.

RANA CATESBEIANA (Bullfrog). **DIET**. *Rana catesbeiana* is known to prey upon a wide range of small vertebrates (Bury and Whelan 1984. U.S. Fish and Wildl. Serv. Publ. 155. U.S. Dept. Interior, Washington, D.C.). Herein I report predation on *Thamnophis atratus hydrophilus*, *Elgaria multicarinata*, *Sceloporus occidentalis*, and *Rana boylii*, species previously unreported as prey. Voucher specimens are catalogued into the California Academy of Sciences (CAS).

On 24 June 1997, I collected a male *R. catesbeiana* (134.1 mm SVL, 298.3 g, CAS 203708) in Cache Creek, Colusa County, California, USA (38°55'29"N, 122°19'54"W) that contained a *Thamnophis atratus hydrophilus* (392 mm SVL, 515 mm total length, 22.7 g, CAS 204236).

On 6 September 1997, I collected a female *R. catesbeiana* (80.7 mm SVL, 59.65 g, CAS 203709) in Bear Creek, Colusa County, California (38°03'24"N, 122°24'41"W) that contained a *Sceloporus occidentalis* (31 mm SVL, 1.5 g, CAS 204238).

On 13 May 1997, I collected a female *R. catesbeiana* (128.8 mm SVL, 288.9 g) in Davis Creek, Yolo County, California (38°53'36"N 122°22'01"W) that contained an *Elgaria multicarinata* (54.8 mm SVL, 2.28 g, with a 9.3 mm tail remnant, CAS 204237). The bullfrog was not retained.

Also on 13 May 1997 at the Davis Creek site, I observed a male *R. catesbeiana* (105 mm SVL, CAS 203633) at 2230 h behaving in a manner consistent with subduing and swallowing moving prey. I hand-grabbed the frog and as I squeezed it for a more secure grasp, the hind feet of another anuran protruded from its mouth. I grabbed the feet and pulled a female *Rana boylii* (45 mm SVL, CAS 203634) from the stomach of the *R. catesbeiana*. The *R. boylii* appeared unharmed and lived until preserved the next morning. The *R. catesbeiana* also contained the partially digested body of another *R. boylii* (CAS numbers pending).

Moyle (1973. Copeia 1973:18–22) inferred that predation by *R. catesbeiana* was a causal factor in the decline and/or disappearance of native ranid frogs, including *R. boylii*, in parts of California. However, he and subsequent authors (Hayes and Jennings 1986. J. Herpetol. 20:490–509; Kupferberg 1997. Ecology 78:1736–1751) who have examined the issue of competition between *R. catesbeiana* and *R. boylii*, offered no direct evidence of predation by *R. catesbeiana* in the field. It is notable that the *R. catesbeiana* that ate the *R. boylii* was smaller than most individuals from a series of adults collected in the watershed (mean = 128.3 mm SVL; range = 81.4–175.7 mm SVL; SD = 22.7 mm; N = 43); thus most adult *R. catesbeiana* present can be assumed capable of preying on *R. boylii*.

I thank Ray Krause of the Homestake Mine and Paul Elliott of the Payne Ranch for access to collecting sites, and Patrick Davis, Roger Hothem, Mark Jennings, and Norm Scott for help collecting specimens. Specimens were obtained under scientific collecting permits issued by the California Department of Fish and Game.

ZACHAENUS PARVULUS (Leaf Frog)**. DEFENSIVE BEHAVIOR and COLOR PATTERN**. Certain leaf-litter leptodactylids (e.g., *Proceratophrys appendiculata*) and microhylids (e.g., *Stereocyclops incrassatus*) display a defensive behavior in which they flatten their body and become immobile, thus acquiring a leaf-like body shape. Together with cryptic coloration, this position should help prevent detection by visually oriented predators (Sazima 1978. Biotropica 10:158). Sazima (*op. cit.*) reported similar behavior by *Zachaenus parvulus*, a leptrodactylid frog endemic to the Atlantic Rainforest of SE Brazil. However, because of the restricted number of observations, he provided only scant details. Here we report field observations of the defensive behavior of *Z. parvulus* and include information on color pattern variation in living frogs.

These observations were made at the Atlantic Rainforest area of Ilha Grande (23°11'S, 44°12'W), an island in southern Rio de Janeiro State, southeastern Brazil. On several occasions (N = 14) we observed *Z. parvulus* display the following behavior: when disturbed they jumped 10–15 cm and, just after landing, remained immobile with the forelimbs and hindlimbs fully extended forward and backwards, the extended limbs remaining along the axis of the body with the body flattened against the ground. If touched, individuals remained immobile and maintained this posture even if overturned. This behavior, together with the color pattern, results in individuals resembling a fallen leaf. During another observation, one individual did not display this complete behavioral sequence but only flattened the body against the ground (MASA, pers. obs.).

Lutz (1944. Bol. Mus. Nac. Rio de Janeiro 17:1–66) provided the only information on the color pattern of *Z. parvulus* in life and reported the dorsal color could be greenish, yellowish, light-wine, or brown. Live individuals in the Ilha Grande population have considerable variation in dorsal color pattern. Of 17 individuals examined 6 (35.3%) were beige with dark-gray bands, 5 (29.4%) light gray, 3 (17.6%) orange, 2 (11.8%) dark-gray, and 1 (5.9%) light-green. Preserved individuals lose their original color after a few days in preservative (pers. obs.). The preferred microhabitat of *Z. parvulus* at Ilha Grande is under fallen tree trunks where various colored fungi are common.

We thank the Sub-Reitoria de Pós-Graduação e Pesquisa (SR-2) for partial funding and the people of the Centro de Estudos Ambientais e Desenvolvimento Sustentado of Campus Regional da Ilha Grande for logistical support. During this study CFDR, MVS, HGB, and MASA received research grants from the Conselho Nacional do Desenvolvimento Científico e Tecnológico - CNPq and DV received a graduate fellowship from Coordenação de Pessoal de Ensino Superior (CAPES).

TESTUDINES

APALONE SPINIFERA (Spiny Softshell) **REPRODUCTION.** Despite considerable data on reproduction in *Apalone spinifera* (reviewed by Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 578 pp.), Iverson (1992. Herpetol. Monogr. 6:25–42) was unable to determine relative clutch mass (RCM) for any species of Trionychidae without having to resort to an estimate. Moreover, he was able to estimate RCM only for the smooth softshell (*A. mutica*). The general absence of information on RCM reflects the difficulty in catching these wary turtles during their nesting forays.

On 10 June 1997, we captured a large female *A. spinifera* just after it had emerged from Stump Lake, a backwater of the Illinois River in Jersey County, Illinois, USA. Despite numerous observations of females at this and other sites, this was the only nesting individual we caught in four years of collecting. Because so little information exists on the relationship between female mass and clutch mass in the Trionychidae, we report details on the female and her clutch.

The female's carapace length was 402 mm measured to the nearest mm with calipers and her gravid mass was 5625 g determined to the nearest 25 g with a spring balance immediately after capture. After injection with oxytocin (Ewert and Legler 1978. Herpetologica 34:314–318), she oviposited 31 nearly spherical eggs over a three day span. The female was retained for another five days and then reinjected. However, she laid no additional eggs and was later released at the collecting site.

The eggs were weighed (nearest 0.01 g) and measured (nearest 0.1 mm) shortly after laying. Average egg mass (mean ± SD, [range]) was 7.92 ± 0.37 g (6.72–8.39 g) and average egg diameter was 24.1 ± 0.55 mm (22.7–25.0 mm). The entire clutch weighed 245.39 g. Relative clutch mass was 4.56% of maternal spent body mass when calculated using the method of Iverson and Smith (1993. Copeia 1993:1–21).

The value of RCM for this turtle was about half that estimated for *A. mutica* (9.03% of maternal spent body mass) by Iverson (*op. cit.*). However, the *A. spinifera* that we studied was much larger than the *A. mutica* (carapace length = ~211 mm, mass = ~819 g) Iverson used to estimate RCM. Iverson (*op. cit.*) found that larger species produce relatively lighter clutches and thus have lower values of RCM than smaller species.

Funding for DAW was provided by a summer internship from the Department of Zoology and Genetics, Iowa State University and by an Iowa State University research grant to F. J. Janzen. This work was partially supported by the Illinois Natural History Survey and the Upper Mississippi River System Long Term Resource Monitoring Program.

CARETTA CARETTA (Loggerhead Sea Turtle). **PREDATION.** Birds are well known predators of hatchling sea turtles (Dodd 1988. U.S. Fish Wildl. Serv. Biol. Rep. 88:1–110). On 26 August 1997, a Caretta Research Project team witnessed a great horned owl (*Bubo virginianus*) feeding upon *Caretta caretta* hatchlings at Wassaw National Wildlife Refuge, Georgia, USA. Weather conditions were clear and the air was warm (28°C) and humid. At 2103 h, hatchlings began to emerge from their nest chamber located in a self release hatchery. During this time, an adult *B.virginianus* flew down and began seizing *Caretta* hatchlings. After catching a hatchling, the owl would transfer the loggerhead from its talons into its mouth and fly to a nearby slash pine tree (*Pinus elliottii*) where it would eat the turtle. This process was repeated five times, and each turtle was seized before it emerged from the dune vegetation bordering the high water mark. By 2118 h, the surviving turtles from this nest had reached the sea and the owl had left the hatchery area. On 27 August 1997, between 2240–2300 h, four more *Caretta* hatchlings were caught and consumed by *B. virginianus* (presumably the same individual). The owl's feeding sequence mirrored the previous night's events.

Great horned owls commonly feed upon small reptiles (Ross 1989. Amphibians and Reptiles in the Diets of North American Raptors. Wisconsin Endangered Species Report No. 59). However, sea turtles have not been documented in the diet of *B. virginianus*. Additionally, these observations are of interest because they demonstrate predation in "protected" hatchery areas. The utilization of hatcheries as feeding territories has been documented for raccoons (*Procyon lotor*) and imported fire ants (*Solenopsis invicta*) but not for any type of avian predator (Dodd 1988, *op. cit.*; Moulis 1997. Chel. Biol. Cons. 2:433–436).

Submitted by **MICHAEL G. FRICK**, Caretta Research Project, P.O. Box 661, Tybee Island, Georgia 31328, USA; e-mail: Caretta05@aol.com.

CHELYDRA SERPENTINA (Common Snapping Turtle). **PREDATION.** Since its introduction into North America in the 1930's, the South American fire ant, *Solenopsis invicta*, has spread throughout the southeastern United States. Fire ants have been observed interfering with a nesting turtle (Whiting 1994. Herpetol. Rev. 25:25), and preying on tortoises (Landers et. al. 1980. Herpetologica 36:353–361), alligators, (Allen et al. 1997. J. Herpetol. 31:318–321) and other species of reptiles (Mount et al. 1981. J. Alabama Acad. Sci. 52:71–78). On 19 September 1992, I discovered a nest of *Chelydra serpentina* along the north shore of the Little Cahaba River, ca. 1.7 km upstream from its junction with the Cahaba River, in Jefferson Co., Alabama. Six dead hatchlings were found on or just below the surface of the nest. A large number of fire ants were on and among the hatchling snapping turtles. The nest did not appear to have been disturbed by a vertebrate predator as there was no excavation of soil at the site, and the turtles were intact with no visible injuries. All of the turtles had a prominent plastral yolk sac of an appropriate size for a hatchling, and otherwise appeared to have developed fully and normally. They appeared to have died shortly before their discovery since there was no noticeable odor or other evidence of decomposition. The presence of a large (>30 cm diameter) fire ant mound about 1 m from the nest indicates that the ants were in close proximity to the nest during a substantial segment of the incubation period. A number of empty eggshells and two intact infertile eggs were found at the site, indicating that some hatchlings may have successfully emerged from this nest. I thank Larry Zorns for companionship in the field.

Submitted by **J. STEVEN CONNERS**, Animal Science Department, Miami Metrozoo, 12400 SW 152nd Street, Miami, Florida 33177, USA.

ERETMOCHELYS IMBRICATA (Hawksbill). **PREDATION.** Necropsy of an immature female hawksbill, *Eretmochelys imbricata*, found stranded in the Florida Keys suggest that shark attack was the ultimate cause of death. The turtle had been found stranded at the furthest point south of Old Boca Chica Road on Boca Chica Key in Monroe County, Florida, USA (24°335'N, 81°412'W). It was stored frozen at the Department of Environmental Protection in St. Petersburg, Florida, until the necropsy in February 1997. The necropsy revealed that the turtle was an immature female (66.8 cm SCL). Upon dissection, deep wounds consistent with shark attack were observed. The tail and posterior marginal scutes along the right side of the carapace were missing as a result of the shark bite, and the right rear flipper was severed. Puncture marks from the attack also appeared on the left rear flipper. The bites of the shark penetrated the body cavity through the abdominal muscles. Shark bite marks on the posterior body portion suggest that the turtle may have been hiding under a coral shelf or attempting to flee its predator when attacked (e.g., Bustard 1983. *In* Harless and Morlock [eds.], Turtles: Perspectives and Research, pp. 234–235). The shark bites appeared to have led to an internal infection in the body cavity, evident from necrotic tissue found in the posterior third of the body. The infection of the tissues implies that the proximate cause of death of the animal was the persistant internal infection, rather than the shark attack itself.

Sharks are known predators of hawksbills, but their impact on hawksbill populations is unknown (Witzell 1983. FAO Fish. Sinop. 137, Rome, p. 77). Young (1992. Marine Turtle Newsletter 59:14) reports remains of a "dinner-plate" sized hawksbill found in the stomach of a tiger shark, *Galeocerado cuvier*, in the Miskito Keys. A juvenile hawksbill was recently found in the stomach of *G. cuvier* in the western Atlantic Ocean (Gasparini and Sazima 1995. Herpetol. Rev. 26:34). My observation is notable because of the large size of the attack victim and because the hawksbill appears to have died from the infection following the attack.

Submitted by **LAURA K. ESTEP**, Natural Sciences Collegium, Eckerd College, 4200 54th Avenue South, St. Petersburg, Florida, 33711, USA.

TERRAPENE ORNATA ORNATA (Ornate Box Turtle). **DIET.** There are several reports of *Terrapene ornata* feeding on the carcasses of mammals (Metcalf and Metcalf 1970. Trans. Kansas Acad. Sci. 73:96–117), birds (Blair 1976. Southwest. Nat. 21:89–103), and even other box turtles (Legler 1960. Univ. Kansas Publ., Mus. Nat. Hist. 11:527–669). Here I report the first published observation of an ornate box turtle eating snake carrion. On 13 August 1997, between 1300 and 1400 h, a sudden thunderstorm moved through the area of Valentine National Wildlife Refuge in Cherry Co., Nebraska, USA. Immediately after the storm I was driving east on Hwy 16B spur from the refuge headquarters to Hwy 83, a 13 mile stretch, and I observed numerous DOR and live reptiles on the still wet pavement. In particular, I observed a *T. o. ornata* on the south side of the road chewing on the exposed viscera of a DOR *Thamnophis sirtalis parietalis*. I interrupted this scavening episode when I stopped the car and approached the scene in order to identify the carcass.

I thank Fredric J. Janzen, Brian E. Smith, and Carrie L. Milne for reviewing this note.

Submitted by **JASON J. KOLBE**, Department of Zoology and Genetics, Iowa State University, Ames, Iowa 50011, USA.

TRACHEMYS GAIGEAE (Big Bend Slider). **COURTSHIP BEHAVIOR**. Male courtship in *Trachemys gaigeae* has not been described in detail, although Ernst (1992, Cat. Amer. Amphib. Rept. 538:3) noted that it does not involve foreclaw titillation but rather pursuit from the rear and possible biting by the male. Herein we provide preliminary observations of courtship in captive *T. gaigeae*.

Adult *T. gaigeae* were collected in Socorro and Sierra counties, New Mexico, and Brewster Co., Texas, USA. Three males (137–163 mm straight-line carapace length, SCL) and two females (216 and 224 mm SCL) were maintained in an outdoor artificial pond (610 cm diam. x 78 cm deep) or were housed in pairs for 3–4 days at a time in an aquarium (61 x 37 x 31 cm) for close observation. Total observation time in both the pond and aquarium was ca. 40 h during 1996–97.

Typical pre-courtship behavior exhibited by males in the pond involved trailing of the female along the bottom and cloacal "sniffing." This was quickly followed by the male approaching the female from the front or side (or rarely from above or beneath) with his head and neck fully extended and oriented towards the head of the female. When their heads were <5 cm apart, the male would initiate a rapid, jerky nodding or bobbing motion of his head (2–3 nods/sec). The nodding motion was accompanied by a simultaneous, less-pronounced, side-to-side "wagging" head motion. This

head nodding was done with the mouth closed and without contact between the pair. Male biting or use of foreclaws was never seen during ca. 30 such encounters. Head nodding usually ceased if either turtle surfaced. However, on three occasions involving two different males in the aquarium, we observed the male continue his head-nodding motions up to the water surface as he accompanied a surfacing female. As the head of the male broke the surface, we observed that a thin jet of water was ejected from his nostrils. Although our observations of "nasal squirting" were limited, our impression is that it is directly related to head nodding, but is undetectable when the male is submerged (nasal squirting was never seen during non-courtship activities such as feeding near the surface). Females were generally unresponsive to courting males, although one female gaped and then bit at a persistent male. Males often attempted to mount quiescent females, usually following courtship, but no copulation was ever observed. Observations of head nodding and nasal squirting were made during April–May in the aquarium (water temperature = 20°C); head nodding alone was seen in the pond in January–February (water temperature = 9–15°C). Head nodding and nasal squirting have been previously reported as elements of courtship behavior in neotropical *Trachemys* spp. (Fritz 1990. Salamandra 26:221–245; Seidel and Fritz 1997. Herpetol. Rev. 28:70–72). Based on our observations of *T. gaigeae* and very similar observations by Fritz (1990, *op. cit.*) of "*T. ornata callirostris*," these behavioral elements appear to be analogous to foreclaw vibration in male *T. scripta* (sensu stricto). Additional studies of Mesoamerican sliders, especially those in which snout length is sexually dimorphic, may reveal similar courtship behaviors.

We thank M. E. Seidel and W. G. Degenhardt for loan of the Texas specimens and comments, and C. W. Painter for comments. The New Mexico Department of Game and Fish Share With Wildlife Program partially funded this work.

Submitted by **JAMES N. STUART** and **JENNIFER B. M. MIYASHIRO**, Museum of Southwestern Biology and Department of Education, University of New Mexico, Albuquerque, New Mexico 87131, USA; e-mail (JNS): StuartJN@unm.edu.

AMPHISBAENIA

BLANUS CINEREUS (Iberian Amphisbaenian). **DIET**. *Blanus cinereus* is an amphisbaenid, endemic to the Iberian Peninsula, that is often found in sandy, loose soils in Mediterranean type ecosystems (Barbadillo 1987. La Guía de Incafo de los Anfibios y Reptiles de la Península Ibérica, Islas Baleares y Canarias. Incafo, Madrid, 694 pp.; Salvador 1981. *In* W. Böhme [ed.], Handbuch der Reptilien und Amphibien Europas, pp. 227–289. Aula Verlag, Wiesbaden). Like other amphisbaenians, it has subterranean, secretive habits, and thus few data about its biology are available. In recent years, some studies have focused on the feeding habits of this species, reporting a diet consisting exclusively of small invertebrates, mainly adult and larval insects (max. prey size = 29.3 mm), in accordance with its small-medium size (up to 30 cm in total length) (Gil et al. 1993 J. Herpetol. 27:205–209; López et al. 1991. Herpetologica 47:210–218).

On 20 April 1996, at Navas del Rey (Province of Madrid, Spain), we observed, by lifting a stone, an adult *Blanus cinereus* (SVL = 162 mm) swallowing the tail of a juvenile Spanish wall lizard (*Podarcis hispanica*) (SVL = 39 mm). The *P. hispanica* was concealed in a small cavity in the ground, 21 cm away from the *B. cinereus*. Although the initial attack had not been observed, an examination of the juvenile *P. hispanica* revealed an injury to its left thigh. Thus, it is probable that the attack was initially directed to the lizard's hindlimb, resulting in subsequent tail autotomy. In any case, we can conclude that *Blanus cinereus* occasionally preys upon small vertebrates, our observations being the first record describing such predatory behavior.

Submitted by **LUIS J. BARBADILLO, IÑIGO MARTÍNEZ-SOLANO** and **DAVID G. VALDEMORO**. Departamento de Biología, Facultad de Ciencias, Universidad Autónoma, E-28049 Cantoblanco, Madrid, Spain.

LACERTILIA

ANOLIS CAROLINENSIS (Green Anole). **HERBIVORY.** On 13 September 1996 at Bienville Parish, Louisiana, USA (3 km E Kepler Creek Bridge), an *Anolis carolinensis* was observed feeding on a flower of an aster (Asteraceae). At 1030 h, the lizard bit the head of the flower. After 5 s, the lizard withdrew its head from the flower and licked its pollen-covered snout before resuming feeding. This behavior continued for 2 min, after which the lizard left the flower and was no longer observed. No insects were visible at the flower; apparently the lizard was consuming nectar or pollen. The consumption of nectar and pollen by *A. carolinensis* was noted by Bartlett (1995. Reptiles 2:48–65). Nectarivory by *A. carolinensis* from hummingbird feeders was reported by Liner (1996. Herpetol. Rev. 27:78). Nevertheless, consumption of nectar and pollen by this species remains a little known and seldom observed behavior.

Submitted by **JOHN G. HIMES**, Museum of Life Sciences, Louisiana State University in Shreveport, One University Place, Shreveport, Louisiana 71115-2399, USA.

ANOLIS CAROLINENSIS (Green Anole). **SAUROPHAGY.** On 16 September 1996, an *A. carolinensis* (ca. 55–65 mm SVL) was observed feeding on a dead *Sceloporus undulatus* (56 mm SVL). The sequence of events follows. At 0910 h, as the observer approached, an anole fled under a shrub. A dead *S. undulatus* was discovered on the ground <5 cm from the site where the anole had departed. The carcass was intact except for the lack of distal halves of the right fore and hindlimbs.

At 0915 h, the observer moved 10 m away from the *S. undulatus*, and the *A. carolinensis* returned to the carcass. The anole grasped one of the two limb stumps with its jaws and violently thrashed the carcass in the air for 2–3 s. After the thrashing, the anole released the carcass and swallowed, indicating that feeding was taking place. The thrashing and swallowing sequence took place repeatedly during 10 min of observation. Approximately 100 harvester ants (*Pogonomyrmex* spp.) were on the carcass as well, and thus the thrashing may have been an attempt to remove the ants as well as a piece of flesh.

At 1050 h, the anole was still feeding on the carcass. After 5 min, the anole fled under a shrub due to observer disturbance. At 1105 h, the anole had not returned and the carcass was examined. The proximal right fore and hindlimbs were nearly devoid of flesh.

The cause of death and limb amputation of the *S. undulatus* could not be determined. However, because it is unlikely that an *A. carolinensis* is capable of killing an adult *S. undulatus* and biting through its leg bones, it is probable that the cause of death and amputation of the limbs were unrelated to the anole.

Anolis carolinensis is known to consume large caterpillars of a size similar to small *S. undulatus* (T. Jenssen, pers. comm). However, I know of only one occurrence of natural saurophagy by *A. carolinensis* (on *A. sagrei*) (J. Losos, unpubl. data).

I thank Gregg Henderson for identifying the ants and Laurence M. Hardy for critiquing the manuscript.

Submitted by **JOHN G. HIMES**, Museum of Life Sciences, Louisiana State University in Shreveport, One University Place, Shreveport, Louisiana 71115-2399, USA.

ANOLIS CRISTATELLUS WILEYAE (Virgin Islands Crested Anole). **HERBIVORY.** On Guana Island, British Virgin Islands, at 0730 h on October 1997, we watched an adult female crested anole chewing and swallowing the bright yellow flower of *Tecoma stans*, a naturalized ornamental shrub native to Central America as far north as Texas. Lazell and Perry (Herpetol. Rev. 1997. 28:150) report frugivory in this species, but were misinformed about one plant that we reported the anoles to be eating, *Trichostigma octandra*. We take this opportunity to correct that identification to *Rivina humila* (Phytolaccaceae), "blood berry."

We are indebted to Dr. George Proctor for redetermining this species from a patch the anoles were eating in 1996. They were eating its berries from the same patch in 1997.

Submitted by **JAMES LAZELL** and **NUMI C. MITCHELL**, The Conservation Agency, 6 Swinburne St., Jamestown, Rhode Island 02835, USA.

CNEMIDOPHORUS HYPERYTHRUS (Orange-throated Whiptail) and ***CALLISAURUS DRACONOIDES*** (Zebra-tailed Lizard). **PREDATION and DIET**. Here, we report predation on *Callisaurus draconoides* by *Cnemidophorus hyperythrus*. On 1 July 1997, while conducting fieldwork at "El Comitán," 17 km N of La Paz, Baja California Sur, México, we observed a male *C. hyperythrus* capturing a lizard. We noosed the whiptail (65 mm SVL, 5.32 g) and identified its prey, a hatchling *C. draconoides*, which was still alive in the predator's mouth. *Cnemidophorus hyperythrus* feeds on termites, spiders and a variety of insects (Asplund 1967. Am. Midl. Nat. 77:462–475; Bostic 1966. Herpetologica 22:23–31). Galina (1994. Estudio comparativo de tres especies de lacertilios en un matorral desértico de la región del Cabo, Baja California Sur, México. Master's thesis, Universidad Nacional Autónoma de México, México City. 81 pp.) examined stomach contents of 126 *C. hyperythrus* collected at "El Comitán" during 1987 and found termites to be the main type of prey. In that study no lizards were registered as prey. However, a hatchling *Uta stansburiana* was found in the stomach of a *C. hyperythrus* from San Diego Co., California, USA (Berrian and Banta 1979. Bull. Maryland Herpetol. Soc. 15:61). Our observation confirms that small lizards form an occasional component of the diet of *C. hyperythrus*.

Submitted by **PATRICIA GALINA**, Centro de Investigaciones Biológicas del Noroeste, P.O. Box 128, La Paz, Baja California Sur, México, **CARMEN BLAZQUEZ**, Estación Biológica de Doñana, CSIC, Avda. VEIGA** and **ALFREDO SALVADOR**, Departamento de Ecología Evolutiva, Museo Nacional de Ciencias Naturales, CSIC, José Gutierrez Abascal 2, 28006 Madrid, Spain.

CNEMIDOPHORUS TIGRIS, UTA STANSBURIANA (Western Whiptail, Side-blotched Lizard). **ENDOPARASITES FROM MÉXICO.** Endoparasites have been reported from *Cnemidophorus tigris* and *Uta stansburiana* from the USA (Telford 1970. Am. Midl. Nat. 83:516–554; Goldberg et al. 1997. Great Basin Nat. 57:273–277). However, there are no reports of helminths from these lizards in México. The purpose of this note is to report the presence of the nematodes *Skrjabinoptera phrynosoma* and *Thubunaea ctenosauri* in *Cnemidophorus tigris* and *Uta stansburiana* from Chihuahua, México. *Cnemidophorus tigris* (N = 4) and *U. stansburiana* (N = 6) were collected 10 km N Laboratorio del Desierto, Mapimí Biosphere Reserve (26°50'N, 103°49'W), Chihuahua, México in 1990. Lizards were fixed in 10% formalin and preserved in 70% ethanol. They were deposited in the herpetology collection of the Instituto de Ecología, A.C., Centro Regional Durango, Durango, México. Upon dissection, nematodes were found in the stomachs of these lizards. Each nematode was placed in a drop of glycerol on a glass slide and identified. Prevalence (number infected individuals divided by number of individuals examined) of *S. phrynosoma* was 50% for *C. tigris* and 67% for *U. stansburiana;* prevalence of *T. ctenosauri* was 50% for *C. tigris* and 33% for *U. stansburiana.* Mean intensity (mean number parasites per infected host) for *S. phrynosoma* was 14.0 in *C. tigris* and 2.5 in *U. stansburiana;* for *T. ctenosauri,* 22.0 in *C. tigris* and 1.5 in *U. stansburiana.* Selected nematodes were placed in vials of alcohol and deposited in the U.S. National Parasite Collection, Beltsville, Maryland: *C. tigris* (*S. phrynosoma* USNPC 87782, *T. ctenosauri* USNPC 87783); *U. stansburiana* (*S. phrynosoma* USNPC 87784, *T. ctenosauri* USNPC 87785).

Skrjabinoptera phrynosoma was originally described (Ortlepp 1922. Proc. Zool. Soc. Lond. pp. 999–1107) from nematodes obtained from *Phrynosoma cornutum* and *P. solare* that died in the London Zoological Garden. It has been found in *C. tigris* in California (Telford 1970, *op. cit.*); however, *U. stansburiana* is a new host record. *Thubunaea ctenosauri* was originally described from *Ctenosaura pectinata* from Aguamilpa, Nayarit, México (Moravec et al. 1997. J. Helm. Soc. Washington 64[2]:240–247). *Cnemidophorus tigris* and *U. stansburiana* are new host records for *T. ctenosauri*.

Submitted by **STEPHEN R. GOLDBERG,** Department of Biology, Whittier College, Whittier, California 90608, USA, **CHARLES R. BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA, and **HECTOR GADSDEN ESPARZA,** Instituto de Ecologia, A.C., Centro Regional Durango, C.P. 34100, A.P. 632, Durango, Durango, México.

CRICOSAURA TYPICA (Cuban Night Lizard). **ENDOPARASITES.** *Cricosaura typica* is known only from Granma Province and Santiago de Cuba Province, Cuba (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies. Descriptions, Distributions, and Natural History. University of Florida Press, Gainesville. 720 pp.). *Skrjabinodon cricosaurae* was originally described from *Cricosaura typica* (Barus and Coy Otero 1974. Vest. Csk. Spol. Zool. 38[1]:1–12) and is the only helminth known for this host (Coy Otero and Barus 1979. Acta Sc. Nat. Brno 13[2]:1–43). The purpose of this note is to present prevalence and mean intensity data on *S. cricosaurae* in two *C. typica* populations. Twenty-one *C. typica* were collected in February and June 1996 in La Mula, Santiago de Cuba Province, Cuba; ten were collected in April 1996 from Alegría de Pío, Granma Province, Cuba. Lizards were originally fixed in 10% formalin and later preserved in 70% ethanol. The body cavity was opened and the gastrointestinal tract was excised by cutting across the esophagus and rectum. The esophagus, stomach, small intestines, and large intestines were slit longitudinally and examined separately under a dissecting microscope. Each nematode was removed and placed

in a drop of glycerol on a glass slide. Nematodes were identified from these temporary mounts; all were from the large intestine. Lizards were deposited in the herpetological collection of the Centro Oriental de Ecosistemas y Biodiversidad (BIOECO) in Santiago de Cuba, Cuba.

The prevalence (number of infected individuals divided by number of individuals examined) of *S. cricosaurae* (86%, 18/21) in *C. typica* from La Mula was higher than that (80%, 8/10) in *C. typica* from Alegría de Pío, although not significantly different (Chi-square = 0.16, $P > 0.05$). Also, the mean intensity (mean number parasites per infected host) was higher (5.3 ± 6.7 SD, range 1–28) in *C. typica* from La Mula than that (3.3 ± 4.3 SD, range 1–13) in *C. typica* from Alegría de Pío, but there was no significant difference (t-test = 0.93, $P > 0.05$).

We thank Angel Arias and Rolando Viña for assistance in collecting specimens. AFG thanks Israel and Felicia Méndez for hospitality in their house at La Mula.

Submitted by **STEPHEN R. GOLDBERG**, Department of Biology, Whittier College, Whittier, California 90608, USA, **CHARLES R. BURSEY**, Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA, and **ANSEL FONG G.**, BIOECO, Museo de Historia Natural "Tomas Romay," Enramadas #601, Santiago de Cuba 90100, Cuba.

ELGARIA KINGII NOBILIS (Arizona Alligator Lizard). **COLORATION.** On 28 June 1995, along Turkey Creek in the Gila Wilderness Area, Grant County, New Mexico, RDJ collected a nearly-patternless *Elgaria kingii* (Fig. 1). The specimen is an adult female, 91 mm SVL and 89 mm tail (regenerated). In life, the dorsal and ventral coloration was solid olive-gray (color 42 in Smithe 1975. Naturalist's Color Guide. Amer. Mus. Nat. Hist., New York) with occasional black flecking laterally. Coloration of the labial scales was normal with contrasting, alternating, black and white scales. This is the first *E. kingii* reported with such abnormal coloration. It is catalogued in the Museum of Southwestern Biology at the University of New Mexico (MSB 59639).

FIG. 1. Nearly patternless female *Elgaria kingii* from Grant Co., New Mexico.

Submitted by **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, and **RANDY D. JENNINGS**, Department of Natural Sciences, Western New Mexico University, Silver City, New Mexico 88062, USA.

GALLOTIA CAESARIS (Hierro Canary Island Lizard). **UNUSUAL PREY.** Most lacertids are insectivorous, but there are notable exceptions in *Takydromus* spp. and some of the members of the genus *Gallotia*, which are herbivorous (Arnold 1989. Bull. Br. Mus. Nat. Hist. 55:209–257). These genera have a tricuspid/multicuspid dentition as an adaptation for feeding on plant material. In *Gallotia* spp. the adult diet consists predominantly of flowers, seeds, and fruits, except in *G. atlantica*, which is insectivorous (Molina 1991. Vieraea 20:1–9; Mateo and López-Jurado 1992. Biol. J. Linn. Soc. 46:39–48). However, the stomach contents of a specimen of *Gallotia caesaris* from El Hierro, Canary Island (SVL = 85 mm) included an undigested *Chalcides viridanus* (Scincidae) with a SVL of 57 mm. The presence of a skink as a prey item and its large size are very unusual not only for *Gallotia* spp., but for lacertids in general.

I thank Luis Felipe López-Jurado for donation of the specimen.

HOLASPIS GUENTHERI LAEVIS (East African Fringe-tailed Forest Lizard). **REPRODUCTION**. Between October 1996 and March 1997, the Cologne Aquarium received 8 adult *Holaspis guentheri laevis* (5 males, 3 females). Locality data were given as Arusha, Tanzania, or Tanzania alone. Sex was determined by comparing the base of the tail (swollen in males) and femoral pores (better developed in males). Ventral body coloration was also found to be a sexually dimorphic character, with males having a bright orange belly; in females it is a faint gray-orange.

Initially, the lizards were housed in groups of multiple males and one female; however, males were soon found to be territorial and aggressive, and were subsequently housed in male/female pairs, or singly.

One pair produced a clutch of two eggs on 14 November 1996. After an incubation period of 54 days one egg hatched. Total length of the hatchling was 50 mm, SVL 25 mm, and mass 0.25 g. Coloration of the hatchling was identical to that of the adults, except for having a totally black ventral surface. Unfortunately, the specimen died one day after hatching. The same pair produced clutches consisting of one egg (on 22 December 1996 and 24 February 1997) and two eggs (5 April 1997). None of these eggs hatched. Clutches of two eggs in this species were reported by Dunger (1967. The Nigerian Field 32(2):117–131).

IGUANA IGUANA (Green Iguana). **JUVENILE PREDATION.** Green iguanas have been reported to nest communally as an strategy to decrease predation by terrestrial vertebrates (Rand and Dugan 1983. Copeia 1983:705–711). Iguana nests may be preyed upon by several species (Rand and Robinson 1969. Herpetologica 25:172–174). Juveniles may suffer particularly high predation (Greene et al. 1978. J. Herpetol. 12:169–176.).

During the dry season (April–May) of 1988 the emergence of hatchlings in several breeding aggregations was documented at Hato Masaguaral, a cattle ranch in Guárico State, Venezuela (8°34'N, 67°35'W). While systematically patrolling the breeding

TABLE 1. Predators documented preying on iguanas or with iguana remains in the stomach. Numbers with an asterisk represent events where predators were seen chasing, stalking, or holding pieces of iguana tail. Frequencies marked with an "f" denote more than 10 predation events. *Piaya cayana* was observed on two occasions with unidentified lizard embryos in an advanced stage of development. Predation by *Crocodylus* occurred in outdoor enclosures.

aggregations, incidents of predation on iguana hatchlings were recorded. Patrols were conducted 0800–0930 h and 1630–1800 h for a total of 51 h of observations in 17 days. Other incidental predation events also were recorded, along with stomach contents of road-killed predators on the highway. Prey were classified into three size categories, based upon estimated SVL: Size I <180 mm, Size II 180–239 mm, and Size III ≥240 mm (Rivas, unpubl.).

Table 1 lists species of vertebrates observed preying on iguanas, along with size class of prey and relative frequency of predation. Birds were the most frequent predators (22 species), followed by reptiles (eight species), and mammals (six species). Predation pressure by mammals could, however, be underestimated due to their secretive and nocturnal habits.

The period between the first and last egg hatched was 14 days. During this time, ca. 4800 hatchling iguanas emerged from 120 nests into a dune of ca. 8 ha. This synchrony of hatching produced an invasion of young iguanas into the area. High encounter rate may account for the high number of predation events we observed.

These data suggest that juvenile iguanas suffer heavy predation from birds. This may explain the cryptic behavior of juveniles in tree tops, where they remain motionless for long periods, synchronizing their movements with the canopy wind (Henderson 1974. Herpetologica 30:327–332), as well as the juveniles' habit of sleeping in burrows (Brust 1985. Amer. Zool. 25:7A).

We are in debt to Tomás Blohm for allowing us work in the ranch and the use of facilities. We also thank J. Thorbjarnarson and B. Thomas for providing valuable information. L. Levin and Renee Owens provided useful comments on early versions of the manuscript. This research was sponsored by Wildlife Conservation Society (formerly New York Zoological Society).

OPHISAURUS VENTRALIS (Eastern Glass Lizard). **NOCTURNAL ACTIVITY.** Glass lizards (*Ophisaurus*) are diurnal (Behler and King 1995. National Audubon Society Field Guide to North American Reptiles and Amphibians. Chanticleer Press, New York. 743 pp.), and to our knowledge there are no records of nocturnal activity. Here we report nocturnal activity in *O. ventralis* in the Apalachicola Lowlands of the Florida panhandle.

On 4 July 1997 at 2325 h, an *O. ventralis* was found AOR on SR 67, 1.2 mi. N NFR 107, Liberty Co., Florida, USA (UF Color Slide 109634). Earlier that day it rained continuously from ca. 1600–2000 h. Glass lizards are good burrowers and spend much of their time below ground (Conant and Collins 1991. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed., Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). As a result, one explanation for this unusual nocturnal behavior might include the lizard retreating from extremely damp soil to drier habitat.

TILIQUA RUGOSA (Sleepy Lizard). **MATING BEHAVIOR and NECROPHILIA.** Sleepy lizards are large (30 cm SVL), long-lived skinks from southern Australia. They form monogamous male-female pairs for up to 8 weeks before mating in late spring, and usually choose the same partners in successive years (Bull 1988. Behav. Ecol. Sociobiol. 23:45–49). Since 1992, we have been locating radio-tagged individuals daily during the pairing season (September–December) at a site near Mt. Mary in the mid-north of South Australia (33°55'S, 139°20'E). Adult mortality is very low (Bull 1995. Aust. J. Ecol. 20:393–402). However, on 28 October 1997, at 0930 h, a radio-tagged female was found dead. It appeared that, during the previous afternoon, her head became caught as she tried to crawl through tangled fencing wire, and, exposed to the afternoon sun, she died from hyperthermia. This female was first tagged in 1995 and had been recorded with the same male partner in each of the three years 1995–1997. That male partner was by the side of the dead female when she was discovered. We removed the female from the wire and placed her close by. That evening the male lizard refuged under a bush ca. 5 m from his mate. On 29 October 1997 at 0920 h the male was ca. 60 m from the female. The following observations of the male and his dead mate commenced at 1605 h on that day, when the female had probably been dead for 48 h. The male approached the female, moving towards her head. He walked directly up to her and stopped in a face-to-face position with her, ca. 10 cm from her snout. He remained in this position for 4 min. He then moved forward to within 3 cm of her and began tongue flicking towards her snout for a further 2 min. The male then remained stationary in the snout-to-snout position with the female for 6 min. before placing his snout under the snout of the female and tongue flicking again for 30 s. He then moved directly backwards 5–6 cm, then forwards in a small arc until he reached the left flank of the female. Once there he began gently nudging the female's side with his snout, while continuing to tongue flick. This continued for 1 min., after which the male moved toward the female's back leg, tongue flicking. The tongue flicking continued as the male moved forward again towards middle of the body. He then nudged the front leg, moved away 2–3 cm, walked to the female's back leg and once again tongue flicked this for ca. 15 s. The male then moved off and refuged under a bush 88 m away. The observed interaction between the male and his dead partner lasted 17 min. Six days later, the male was again observed ca. 10 m from the dead female.

We interpreted this interaction as a component of the pair bond that forms between male and female lizards during the spring, and an indication of the strength of the bond. The male still recognized cues from his partner, and remained with her, apparently attempting to elicit normal behavior from her, 48 h after her death. Live pairs use tongue flicking and chemical signals to maintain a close physical association over much of the spring (Bull et al. 1993. Herpetologica 49:294–300). There has been one previous observation in this species (Sharrad et al. 1995. W. Aust. Nat. 20:33–35) where a male was attempting to mate with a road-killed female, although the previous history of that pair was not known.

We thank Nathalie Loussert for help with field observations, and the Australian Research Council for funding the research.

UMA EXSUL, UMA PARAPHYGAS (Fringe-toed Sand Lizard, Chihuahua Fringe-toed Lizard). **ENDOPARASITES.** The fringe-toed sand lizard, *Uma exsul,* is known only from Coahuila, México; the Chihuahua fringe-toed lizard, *Uma paraphygas* is known only from Coahuila and Chihuahua, México (Adest 1977. Copeia 1977:47–52). There are no reports of endoparasites from these hosts. The purpose of this note is to report the presence of the nematode *Skrjabinoptera phrynosoma* in *Uma exsul* and *U. paraphygas*. *Uma exsul* (N = 4) was collected 8 km S Emilano Zapata, Coahuila, México in 1992; *Uma paraphygas* (N = 6) was collected 10 km N Laboratorio del Desierto, Mapimí Biosphere Reserve, Chihuahua, México. Lizards were preserved in 10% formalin and later stored in 70% ethanol. They were deposited in the herpetology collection of the Instituto de Ecología, A.C., Centro Regional Durango, Durango, México. Nematodes were removed from the stomachs of these lizards. Each was placed in a drop of glycerol on a glass slide and identified as *Skrjabinoptera phrynosma.* Prevalence (number infected individuals divided by number of individuals examined) was 100% for both *U. exsul* and *U. paraphygas.* Mean intensity (mean number parasites per infected host) was 4.5 ± 2.7 SD, range = 1–7 for *U. exsul* and 7.5 ± 2.2 SD, range = 5–10. Selected specimens of *Skrjabinoptera phrynosoma* were placed in vials of ethanol and deposited in the U.S. National Parasite Collection, Beltsville, Maryland: *U. exsul* (USNPC 87650);*U. paraphygas* (USNPC 87649) and in Colección Nacional de Helmintos, Instituto de Biología de la Universidad Nacional Autónoma de México: *U. exsul* (CNHE 3202); *U. paraphygas* (CNHE 3203). *Skrjabinoptera phrynosoma* has previously been found in *U. notata* and *U. scoparia* from California (Telford 1970. Am. Midl. Nat. 83:516–554) and other species from México: *Phrynosoma braconnieri, P. taurus* (Goldberg and Bursey 1991. Southwest. Nat. 36:365–368), *P. douglasii, P. solare, Sceloporus spinosus* (Caballero 1937. Ann. Inst. Biol. Univ. Nac. Auton. Mex. 8[1– 2]:189–200) as well as 11 other North American lizard species (see Goldberg and Bursey, *op. cit.*) plus 14 lizard species from Cuba (see Baker 1987. Mem. Univ. Newfoundland, Occas. Pap. Biol. 11:1– 325). The finding of *S. phrynosoma* in *U. exsul* and *U. paraphygas* are new host records.

BURSEY,** Department of Biology, Pennsylvania State University, Shenango Campus, Sharon, Pennsylvania 16146, USA, and **HECTOR GADSDEN ESPARZA,** Instituto de Ecología, A.C., Centro Regional Durango, C.P. 34100, A.P. 632, Durango, Durango, México.

VARANUS EXANTHEMATICUS (Bosc's Monitor). **PREDATION.** On 17 June 1997 at 1535 h we found a burrow in a field of cassava at Bui Camp (8°00'N, 2°15'W), close to Bui National Park, Ghana, that showed signs of use by a young Bosc's monitor (*Varanus exanthematicus*). When we returned at 0630 h the following morning there were signs that a snake had entered the burrow. The burrow was excavated and found to contain an African garter snake, *Elapsoidea guentheri* (602 mm SVL, 44 mm tail, 97 g without prey) that regurgitated a juvenile *V. exanthematicus* (199 mm SVL, 11 mm tail, 32 g). Although we have long suspected that snakes (particularly of the genus *Naja*) are important predators on young monitor lizards, this is the first direct proof of predation by snakes that we have found. Lenz (1995. Zur Biologie und Okologie des Nilwarans, *Varanus niloticus*, im Gambia, Westafrika. Mertensiella 5. 256 pp.) records predation on an adult *V. exanthematicus* by *Python sebae* in The Gambia.

SERPENTES

ARIZONA ELEGANS (Glossy Snake). **DIET.** On 21 June 1997, we excavated an adult female *Arizona elegans* (567 mm SVL, 93 mm TL, 87 g; Fig. 1) from a burrow in sandy soil of the shinnery oak (*Quercus havardii*) habitat 14.8 km S, 18 km W Hobbs, Lea County, New Mexico, USA (32°33.845'N, 103°19.395'W). This snake was maintained in a cooler until it was sacrificed and preserved on 23 June. Dissection of the stomach yielded an adult Ord's kangaroo rat (*Dipodomys ordii*) (124 mm body length, 67 g). Both the snake and prey were weighed and measured after being fixed in 10% formalin and stored in 55% isopropyl alcohol. The prey was 77% of the total weight of the snake. During the three days from the time of capture to the time the specimen was preserved, the girth of the snake became visibly smaller, suggesting the possibility of a larger prey/predator percentage. The snake and prey were deposited in the University of New Mexico Museum of Southwestern Biology, Division of Herpetology (MSB 60802).

FIG. 1. Adult female *Arizona elegans*, indicating relative size of ingested prey, an Ord's kangaroo rat.

CORONELLA GIRONDICA (Southern Smooth Snake). **DIET**. The ecology of European smooth snakes is poorly documented because of their secretive behavior. Of the two species, *Coronella girondica* is more saurophagous than *C. austriaca*. *Coronella girondica* preys mainly on lizards and juvenile snakes, but mammals and arthropods are occasionally taken (Agrimi and Luiselli 1994. Vie Milieu 44:203–210; Galán in press. *In* Ramos [ed.], Fauna Iberica. Vol. Reptiles. MNCN-CSIC, Madrid). Neither of the published works on the diet of *C. girondica* makes reference to predation on birds, which are occasionally taken by *C. austriaca*. (Rugiero et al. 1995. Herpetol. J. 5:316–318). During July 1996 in the Natural Park of Sanabria (Zamora Province, Spain; UTM: 29TPG813655) at an altitude of 1605 m and at dusk (1930 h), we observed an adult *C. girondica* in a dunnock (*Prunella modularis*) nest that had been constructed at the bottom of a shrub. In the snake's coils was a dunnock chick, which the snake was swallowing. After ten minutes the chick was finally devoured. Three other chicks remained in the nest while the parents flew nearby emitting cries of alarm. Smooth snakes may have a constraint on the size of their prey because they cannot unhinge the lower jaw, perhaps forcing the selection of small or elongated prey such as lizards (Dusej 1993. *In* Böhme [ed.], Handbuch der Reptilien und Amphibien Europa. Band 3/1. Schlangen [Serpentes], pp. 247–264. Aula Verlag, Wiesbaden). Our observation of a bird in the diet of *C. girondica* is the first recorded for this species and indicates that chicks or small birds can also be captured. We thank P. Galán and J. M. Pleguezuelos for their comments on the text.

ELAPHE JANSENI (Celebes Black-tailed Ratsnake). **MAXIMUM SIZE.** Records indicate that *Elaphe janseni* commonly reaches a total length of 170–180 cm, and occasionally as much as 200 cm (Schulz 1996. A Monograph of the Colubrid Snakes of the Genus *Elaphe* Fitzinger. Koeltz Scientific Books, Havlickuv Brod, Czech Republic. 439 pp.). A female in the University of Colorado Museum of Natural History (UCM 59364), acquired from central Sulawesi, Indonesia, in November 1997, considerably exceeds those dimensions, measuring 237.4 cm total length (54.2 cm tail length). Although these measurements are impressive, Schulz (*op. cit.*) regards *Elaphe taeniura friesi* of Taiwan as the largest member of the genus, reaching a maximum length of 270 cm.

Submitted by **KAMURAN TEPEDELEN**, P.O. Box 19096, Boulder, Colorado 80308, USA (e-mail: kamuran@aol.com), and **HOBART M. SMITH**, EPO Biology, University of Colorado, Boulder, Colorado 80309-0334, USA (e-mail: hsmith@colorado.edu).

EUNECTES MURINUS (Green Anaconda). **DIET.** The diet of *Eunectes notaeus* was described by Strussman (1994. Stud. Neotr. Fauna Envir. 28:157–168), but little is known about the food habits of *E. murinus* in the wild. During February 1996, during an ecological study of crab-eating foxes (*Cerdocyon thous*) in Emas National Park, central Brazil, a fox fitted with a radio-collar was eaten by an anaconda on the shore of the Rio Formoso. The snake stayed at the capture site for two days (as detected by telemetry data), then swam the 5 m-wide river and entered a gallery forest. We located this anaconda 30 days later, 200 m from the capture site, basking in a marsh. We captured and held the snake in an enclosure until the following day, when it regurgitated the collar and the remains of the fox. After regurgitating the fox remains, the snake measured 3.15 m (total length), 45 cm maximum circumference, and weighed 15 kg. The fox, when originally captured, weighed 7.5 kg. This is the second record of an anaconda preying on a crab-eating fox in the Park. On another occasion, A. M. da Cruz and park rangers observed an anaconda (ca. 4 m total length) eating a crab-eating fox on the bank of the Rio Formoso. In addition, two anecdotal observations of anacondas eating crab-eating foxes have been reported by local inhabitants on farmlands

that surround Emas National Park. Crab-eating foxes spend much time foraging in marsh habitats (Brady. 1979. *In* Eisenberg [ed.], Vertebrate Ecology in the Northern Neotropics, pp. 161–171. Smithsonian Inst. Press, Washington, D.C.), behavior which may expose them to frequent anaconda predation.

We thank José Alexandre F. Diniz Filho for reviewing the manuscript and Antonio Malheiros for additional information on anacondas in Emas National Park. This information was collected during a mammalian carnivore community study in Emas National Park. This research was supported by CENAP/IBAMA, Fundaÿão O Boticário, the Denver Zoo, the Memphis Zoo, and CAPES.

MASTIGODRYAS BIFOSSATUS (Jararaca do Banhado). **TAIL BREAKAGE.** In reptiles, partial loss of the tail may result from two distinct mechanisms: intravertebral rupture (involving both neural control and late tail regeneration), or intervertebral rupture (without neural involvement or tail regeneration). The former occurs widely in lizards (Etheridge 1967. Copeia 1967:699–721), whereas the latter is common in amphisbaenids (Gans 1978. Trans. Zool. Soc. Lond. 34:347–416) and snakes (Mendelson 1992. Herpetologica 48:448–455; Savage and Crother 1989. Zool. J. Linn. Soc. 95:335–362). Both types of tail autotomy may function as antipredator mechanisms (Henderson 1984. *In*: Seigel et al. [eds], Vertebrate Ecology and Systematics: A Tribute to Henry S. Fitch, pp. 185–194. Museum of Natural History, University of Kansas, Lawrence, Kansas; Mendelson, *op. cit.*).

Here we present data on frequencies and characteristics of tail breakage in 119 museum specimens of *Mastigodryas bifossatus* from diverse localities in Brazil. We examined both young and mature specimens of *M. bifossatus*, housed at Instituto Butantan (IB), São Paulo; Museu de Ciências e Tecnologia da Pontifícia Universidade Católica do Rio Grande do Sul (MCP), Porto Alegre; Museu de Ciências Naturais da Fundação Zoobotânica do Rio Grande do Sul (MCN), Porto Alegre; and Linha de Pesquisa em Herpetologia da Pontifícia Universidade Católica do Rio Grande do Sul (LPH), Porto Alegre. For each specimen with a broken tail we recorded the number of remaining subcaudals (SC), sex, and snout-vent length (SVL).

Tail breakage in *M. bifossatus* occurred between SC 32 and 98. It was most common (33.3%) between SC 81 and 90, and rarest (3.7%) between SC 41 and 50. In females, the number of remaining subcaudals ranged from 32–93 (N = 24). For males, this range was 35–98 (N = 30). There were no sex-related differences in the ratio of broken to intact tails ($X^2 = 0.81$).

Among the 119 specimens, 46.7% showed tail loss. In specimens with intact tails, tail length was 31–41% of SVL in females (N = 15, SVL > 600 mm) and 34–44% of SVL in males (N = 16, SVL > 600 mm). For specimens with incomplete tails, tail length was 15–35% of SVL in females (N = 10, SVL > 600 mm), and 10–43% in males (N = 13, SVL > 600 mm). We conclude that *M. bifossatus* can be included among those species of snakes having a high frequency of broken tails. Despite high frequencies of tail breakage, well-defined breakage sites or sex-related breakage patterns are apparently lacking in this species.

We thank the following curators for allowing examination of material under their care: M. Di-Bernardo (MCP), M. Araújo-Leitão (MCN), G. Puorto and M. F. D. Furtado (IB). We also thank T. De Lema for incentive, and C. Strüssmann and J. Ragusa-Netto for important suggestions about the manuscript. Financial support was provided to VLF by the Fundação Coordenação de Aperfeiçoamento de nível Superior (CAPES - Brazilian Federal Government).

Submitted by **VANDA LÚCIA FERREIRA**, Universidade Federal do Mato Grosso do Sul, Centro Universitário de Corumbá (CEUC/DAM), Av. MICRURUS FRONTALIS (Coral Snake). **MALE COMBAT.** Combat rituals have been observed in numerous snake genera, including several elapids (Shine 1994. Copeia 1994:326–346). One explanation for such behavior is male-male competition for access to reproductive females (Bogert and Roth 1966. Amer. Mus. Novit. 2245:1–27; Kelleway 1982. Br. J. Herpetol. 6:225–230).

Micrurus frontalis is an elapid whose reproductive behavior is largely unknown. We report the first observation in the field of a combat ritual between two male *M. frontalis* (SVL = 875 and 836 mm). On 12 April 1994 (ca. 1230 h) in Santa Rita city (29°51'S, 51°16'W), Rio Grande do Sul, Brazil, the snakes were found sheltered under rocks. They were aligned horizontally with their bodies and tails interwined and their heads raised slightly (Fig. 1). The two males kept their heads side by side while moving foward and trying to hover over each other. When captured, one everted the hemipenis. Subsequently, these males were deposited in the Museum Collection of the Museu de Ciências Naturais, Fundação Zoobotânica do Rio Grande do Sul (MCN 11424, 11435).

In addition to our field observation, two captive males were twice observed engaging in a combat ritual in the same season. In every case, the postures were very similar to those of *Austrelapis superbus* (Shine and Allen 1980. Victorian Nat. 97:188–190), but different from those reported for other elapids. The horizontal interwining of the body without vertical posturing of the head and anterior trunk appears similar to the behavior of colubrids such as *Pituophis melanoleucus affinis* (Bogert and Roth, *op. cit.*).

We thank M. G. Salomão for helpful comments and revisions of the manuscript, O. A. V. Marques for fruitful discussions on the subject, and V. X. da Silva for preparing the illustration.

FIG. 1. Combat ritual between male *Micrurus frontalis*.

OPHEODRYS AESTIVUS (Rough Green Snake). **EGG PREDATION**. Since its introduction into North America in the 1930's, the South American fire ant, *Solenopsis invicta*, has spread throughout the southeastern United States. Fire ants have been documented to consume the eggs of the lizard, *Cnemidophorous sexlineatus* (Mount et al. 1981. J. Alabama Acad. Sci. 52:66–70). On 3 July 1994, a clutch of nine *Opheodrys aestivus* eggs was discovered beneath a piece of carpet in Leeds, Jefferson Co., Alabama. The eggs appeared normal in size, shape, and shell development and were slightly adherent. Three of the eggs were separated from the clutch and moved indoors for artificial incubation at 22–29°C. The other six were left undisturbed. The three artificially incubated eggs hatched on 10 August. By 12 August, fire ants had built a small mound on the undisturbed eggs, and at least four were oozing clear fluid from tiny punctures. By 23 August two eggs had collapsed and all were removed for examination/artificial incubation. By 29 August all the eggs but one had collapsed. This egg produced a viable hatchling on 30 August. It is probable that the fire ants were directly responsible for the failure of the five eggs to incubate properly. I thank Kurt Buhlmann for a valuable reference.

Submitted by **J. STEVEN CONNERS**, Animal Science Department, Miami Metrozoo, 12400 SW 152nd Street, Miami, Florida 33177, USA.

OXYBELIS FULGIDUS (Green Vine Snake or Bejucillo). **FEEDING.** On 6 June 1996 at ca. 1130 h we encountered an adult (ca. 1.7 m total length) *Oxybelis fulgidus* ca. 1.3 m above the forest floor in the dense understory of second growth forest in the Selva Verde private reserve, Chilamate, Heredia Province, Costa Rica. The snake was draped across three different small trees. It then moved horizontally for about 1 m, turned 180°, and descended at a 30° angle ca. 0.7 m before pausing. From this position the snake moved slowly at first, then rapidly forward and down ca. 0.5 m, striking a large (ca. 9.5 cm SVL) *Ameiva festiva festiva*. The snake seized the lizard by combining forward movement of its body with a rapid strike of its head. The struggling lizard was grasped across the body between the fore and hind legs. Next the snake moved its prey toward the back of its mouth using alternating movements of its upper and lower mandibles, probably envenoming the lizard at this time. During this process the snake moved from its extended downward position to a horizontal position. The alternating movements of the upper and lower mandibles continued, now positioning the lizard, which had stopped struggling, to be swallowed head first. After swallowing the lizard until only 2 cm of the tail protruded from the snake's mouth, it climbed a small tree to a branch that formed an acute angle with the trunk. It lifted its head and ca. 4 cm of its neck over the branch and began to move its body through the narrowest portion of the fork, which was too narrow to permit passage of the lump that was the lizard's body. In this way the lizard was pushed down the snake's esophagus. The snake pushed the bulge ca. 6 cm distally, then stopped moving. The lizard's tail was no longer visible in the snake's mouth. When we left 5 min later, the snake was still poised motionless in the fork of the tree. The observation is noteworthy in that the capture was unusually low (ca. 20 cm) for a species of *Oxybelis* (Henderson and Binder 1980. Milwaukee Publ. Mus. Contr. Biol. Geol. 37:1–38) and the snake appeared to use the tree fork to assist in swallowing the unusually large prey.

We thank Bryan L. Sharp and Gregory J. Colwell for assistance with identification of the snake and its prey. Bruce C. Jayne and A. John Gatz provided helpful comments on the manuscript.

Submitted by **JEFFREY L. NORRIS**, APDO 178-3006, Heredia, Costa Rica, and **EDWARD H. BURTT, JR.**, Department of Zoology, Ohio Wesleyan University, Delaware, Ohio 43015-2370, USA.

THAMNOPHIS MELANOGASTER CANESCENS (Mexican Black-Bellied Garter Snake). **LITTER SIZE**. On 22 July 1995, a gravid female *T. melanogaster canescens* was found in Lake Pátzcuaro (19°32'N and 101°43'W) in the state of Michoacán, México. This lake is 19.75 km in length and 2035 m in elevation. The pregnant snake was measured and weighed, and then its embryos were removed and were individually measured and weighed. The adult female measured 506 mm SVL, 136 mm tail length (TL), weighed 134.6 g, and contained 12 embryos. The measurements of the embryos were: mass (mean ± SE [range]) = 2.21 ± 0.083 (1.44–2.54); SVL = 118.3 ± 1.4 mm (108–128 mm); TL = 37.0 ± 0.8 mm (34–42 mm). This litter size is similar to other females (mean = 12.9 embryos) cited by Ford and Ball (1977. Herpetol. Rev. 8:118).

WANTED: FIELD HERPETOLOGIST

National Company has several Part-time Positions open throughout the U.S. For a detailed Position Description and/or to find out if there are openings in your region, send a stamped, self-addressed envelope to **Michael Weeks, P.O. Box 914, Galesburg, Illinois 61402-0914.**

GEOGRAPHIC DISTRIBUTION

Instructions for contributors to Geographic Distribution appear in Volume 29, Number 1 (March 1998).

GYMNOPHIONA

LUTKENOTYPHLUS BRASILIENSIS (São Paulo Caecilian). ARGENTINA: MISIONES: 25 de Mayo, Puerto Londero (27°23'S, 54°26'W). September 1947. M. J. Viana. Museo Argentino de Ciencias Naturales, Buenos Aires (MACN 9491). Verified by G. Carrizo. First record for country; extends range 165 km S from nearest previous record at Ciudad del Este, Itaipu, Paraguay (Nussbaum 1986, J. Herpetol. 20:441–444).

Submitted by **TAMARA HEER** and **LLAURA LANARI**, Museo Argentino de Ciencias Naturales, Sección de Herpetología, Avenida Angel Gallardo 470, Buenos Aires, Argentina (e-mail: frida298@yahoo.com).

CAUDATA

AMBYSTOMA CINGULATUM (Flatwoods Salamander). USA: GEORGIA: Miller Co: Willoughby Tract of Mayhaw Wildlife Management Area (31°13'N, 84°47'W). Exact location withheld due to the rarity of the species. 6 March 1998. John B. Jensen. University of Georgia Museum of Natural History (UGAMNH 40092). Verified by M. E. McGhee. First county record. Two larvae were captured in an isolated cypress (*Taxodium ascendens*) pond surrounded by longleaf pine (*Pinus palustris*)/wiregrass (*Aristida beyrichiana*) flatwoods.

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john_jensen@mail.dnr.state.ga.us) and **STEVE A. JOHNSON**, Department of Wildlife Ecology and Conservation, University of Florida, 303 Newins-Ziegler Hall, Gainesville, Florida 32611-0430, USA (e-mail: tadpole@ufl.edu).

AMBYSTOMA TALPOIDEUM (Mole Salamander). USA: GEORGIA: White Co: Smithgall Woods Conservation Center, ca. 2 km ESE jct. of State Rt. Alt. 75 and State Rt. 348. 28 January 1998. John B. Jensen. UGAMNH 40061–63. Verified by M. E. McGhee. First county record and first Georgia record within the Blue Ridge physiographic province (Williamson and Moulis 1994, Savannah Sci. Mus. Publ. 3:1–712). Many paedomorphic adults observed actively breeding in a woodland pool within the Dukes Creek floodplain.

Submitted by **JOHN B. JENSEN**, Georgia Department of Natural Resources, Nongame-Endangered Wildlife Program, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john_jensen@mail.dnr.state.ga.us).

AMPHIUMA PHOLETER (One-toed Amphiuma). USA: MISSISSIPPI: Jackson Co: Mississippi Sandhill Crane National Wildlife Refuge: SE 1/4 of SE 1/4 Sec. 11, T7S, R8W, 0.2 km W of W boundary of Old Fort Bayou Mitigation Bank, 0.35 km S of I-10, ca. 1.72 km W of I-10 bridge spanning Old Fort Bayou. 14 March 1998. Peter S. Floyd, Sr. Mississippi Museum of Science Collection (MMNS 5409). Verified by D. Bruce Means. Specimen found dead and partly decomposed in a shallow stream bordered by longleaf and slash pine; mat of sphagnum moss present on bank above collection site. Stream drained into cypress tupelo gum swamp ca. 100 m downstream from collection site. Substrate in the stream and swamp is relatively firm and interlaced with roots. First record for the state of Mississippi and westernmost locality for the species (Means 1996, Cat. Am. Amphib. Rept. 622.1–622.2).

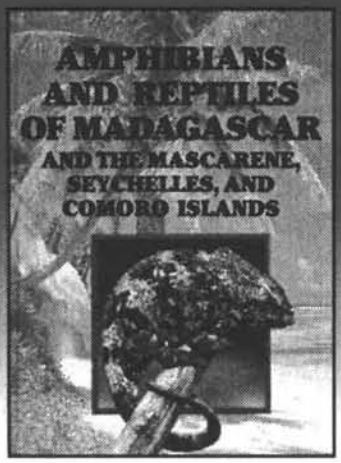
Submitted by **PETER S. FLOYD, SR., PETER S. FLOYD, JR.,** and **JONATHAN D. FLOYD**, Mississippi Museum of Natural Science, 111 North Jefferson Street, Jackson, Mississippi 39201, USA.

DICAMPTODON COPEI (Cope's Giant Salamander). USA: WASHINGTON: Skamania Co: Spring Creek National Fish Hatchery, 2 km W of White Salmon River (SW1/4 Sec. 22, T3N, R10E). On 29 March 1998, we collected one neotenic larva (UMMZ 222695–222696) in each of two unbaited minnow-traps set overnight in a spring-fed creek where it emerges from the base of a forested, talus slope. Verified by Lawrence L. C. Jones. Extends the known distribution ca. 25 km E in the Columbia River Gorge (Nussbaum et al. 1983, Amphibians and Reptiles of the Pacific Northwest. Univ. Press Idaho, Moscow. 332 pp.; McAllister 1995, Northwest Fauna 3:81–112).

Submitted by **WILLIAM P. LEONARD**, Washington Department of Ecology, P.O. Box 47775, Olympia, Washington 98504-7775, USA, **LAURA L. TODD**, U.S. Fish and Wildlife Service, 2600 SE 98th Avenue, Suite 100, Portland, Oregon 97266, USA, and **MEGAN A. LEONARD**, 223 Foote Street NW, Olympia, Washington 98502, USA.

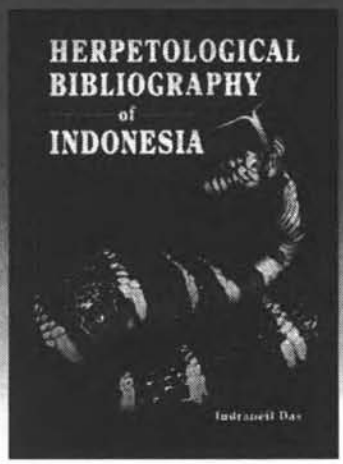
ENSATINA ESCHSCHOLTZII (Ensatina). USA: WASHINGTON: Klickitat Co: NW 1/4, NW 1/4, Sec 20, T4N, R10E, 20 m W of road B-1600. 23 April 1998. Suzanne Grayson. UWBM Color Print 2293 (juvenile). Verified by Keith B. Aubry. One adult and one juvenile were found under surface objects in a Douglas-fir forest with a vine maple understory. First county record and first record of this species east of the Cascade Crest in Washington, as indicated by county lines (McAllister 1995, Northwest Fauna 3:81–112).

Submitted by **LAWRENCE L. C. JONES**, USDA Forest Service, Pacific Northwest Research Station, 3625 93rd Avenue SW, Olympia, Washington 98512, USA, and **SUZANNE GRAYSON**, Washington Department of Natural Resources, 713 East Bowers Road, Ellensburg, Washington 98926, USA.



NOTOPHTHALMUS PERSTRIATUS (Striped Newt). USA: GEORGIA: Emanuel Co: Ohoopee Dunes Natural Area (Georgia Department of Natural Resources), ca. 8.2 km WNW Swainsboro (32°36'19"N, 82°25'04"). 24 August 1997. Dirk J. Stevenson and Beth A. Willis. UGAMNH 40086–89. Verified by M. E. McGhee. Larvae collected at isolated, 1.6 ha semi-permanent pond fringed with swamp blackgum (*Nyssa biflora*). Surrounding habitat represented by xeric longleaf pine (*Pinus palustris*)—turkey oak (*Quercus laevis*)—wiregrass (*Aristida beyrichiana*) sandhill. 24 January 1998. Mark A. Bailey, John B. Jensen, Alison J. McGhee, Dirk J. Stevenson, and Keith R. Tassin. UGAMNH 40090–91. Verified by M. E. McGhee. Sixteen adults, including nine perennibranch individuals, were captured (1 perennibranch adult and 1 metamorphic adult preserved). Females (N = 6) averaged 38 mm SVL (range 35–40 mm) and averaged 1.43 g in weight (range 1.19–1.58 g); males (N = 10) averaged 36 mm SVL (range 31–38 mm) and 1.14 g in weight (range 0.66–1.45 g). First vouchered records for this county, and extend known range ca. 48 km WSW of nearest known locality in Jenkins County, Georgia (Williamson and Moulis 1994, Savannah Sci. Mus. Publ. 3:1–

Recent Releases From Krieger



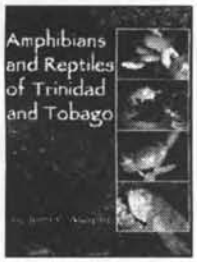
A KANSAS SNAKE COMMUNITY:
Composition and Changes Over 50 Years
by Henry S. Fitch
176 pp. $42.50

A Kansas Snake Community summarizes findings from a field study of 50 consecutive years on the 18 species of snakes found on the University of Kansas Natural History Reservation and adjoining sections of land.

AMPHIBIANS AND REPTILES OF MADAGASCAR
AND THE MASCARENE, SEYCHELLES, AND COMORO ISLANDS
by Friedrich-Wilhelm Henkel & Wolfgang Schmidt
336 pp. $64.50

This work is a very accessible guide to the herpetofauna of the area and comes complete with information on the regional climate and vegetation, as well as with information on vivarium care.

HERPETOLOGICAL BIBLIOGRAPHY OF INDONESIA
by Indraneil Das
96 pp. $22.50



This work is a comprehensive bibliography of the scientific papers, magazine and newspaper articles, books, book reviews, museum catalogues, bibliographies, chapters from books, and theses that contain references to any species of amphibians and reptiles in this region.

BRYAN**, Division of Natural Science, Bossier Parish Community College, 2719 Airline Drive North, Bossier City, Louisiana 71111, USA.

BUFO FERNANDEZAE. ARGENTINA: CÓRDOBA: Barreto (33°20'43"S, 63°18'20"W), temporary pond at Km 148, Ruta Provincial No. 4., 153 m. 26 January 1995. A. L. Martino. Herpetologial Collection of Universidad Nacional de Río Cuarto, Ecología (UNRC-ECO 616–17); 28 January 1998 (in amplexus)—male 43.4 mm, female 46.5 mm, snout-vent length. UNRC-ECO 613–15. All verified by R. Martori. Species previously recorded in eastern part of Córdoba province as *Bufo granulosus fernandezae* (di Tada et al. 1976, Bol. Acad. Nac. Cs. Córdoba 51[3–4]:325–362) and as *Bufo fernandezae* (Cei 1980, Monitore Zool. Ital. N. S. Monog. No 2. 2609 pp.; Lavilla et al. 1992, Asoc. Herpetol. Argentina Serie Divulgación No. 7. 18 pp.; di Tada et al. 1996, pp. 191–213. *In* I. E. di Tada and E. H. Bucher (eds.). Ed. UNRC). Range extension.

Submitted by **ADOLFO L. MARTINO, NANCY E. SALAS**, and **ISMAEL E. DI TADA**, Ecología, Departamento de Ciencias Naturales, Facultad de Ciencias Exactas, Físico-Químicas y Naturales, Universidad Nacional de Río Cuarto, Km 601, Ruta Nacional No. 36, (5800) Río Cuarto, Córdoba, Argentina (e-mail: amartino@exa.unrc.edu.ar).

CTENOPHRYNE GEAYI (Brown Egg Frog). FRENCH GUIANA: COMMUNE DE ROURA: Crique Bagot, foot of the Kwata Mountain (4°32'N; 52°32'W, elev. 10 m). 5 January 1995. Philippe Kok. Institut royal des Sciences naturelles de Belgique (IRSNB 12731). Verified by G. Lenglet. New county record, previously known only from two localities in French Guiana—the Sinnamary River basin (commune de Saint-Elie) and 'Saut Emerillonî, upper Inini River (commune de Maripasoula) (de Massary and Lescure 1998, Revue fr. Aquariol. 25[1–2]:53–57). Extends range ca. 60 km airline SE from the easternmost known locality in French Guiana. Rare species probably due to its secretive habits; the specimen (34.4 mm SVL) was collected by day under dead leaves.

Submitted by **PHILIPPE KOK**, Laboratoire dí Herpétologie, Institut royal des Sciences naturelles de Belgique, 29 rue Vautier, B-1000 Bruxelles, Belgium.

ELEUTHERODACTYLUS LAURASTER (NCN). NICARAGUA: MATAGALPA: Selva Negra, 1300 m elev. (12°59"96'N, 85°54"55'W). March and August 1995, March and April 1996. G. Köhler. July and August 1997. P. Stoldt. Forschungsinstitut und Naturmuseum Senckenberg (SMF 77851, 77853–4, 77233–46, 78229–32). Verified by James R. McCranie. First records for Nicaragua; extends the range ca. 200 km south of the closest known locality in Honduras (Savage et al. 1996, Proc. Biol. Soc. Washington 109:366–372).

Submitted by **GUNTHER KÖHLER**, Forschungsinstitut und Naturmuseum Senckenberg, Sektion Herpetologie, Senckenberganlage 25, D-60325 Frankfurt a.M., Germany.

HYLA CINEREA (Green Treefrog). USA: TEXAS: ARKANSAS CO: Arkansas Wildlife Refuge. 12 April 1986. A. Chaney and party. TAIC 5666. Verified by Steve A. Smith. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **MICHAEL JAMES McCOID**, Department of Biology, Campus Box 158, Texas A&M University, Kingsville, Texas 78363, USA.

HYLA PUNCTATA. BRAZIL: PARANÁ: Diamante do Norte Municipality (ca. 22°40'S, 53°00'W). 5 March 1998. P. S. Bernarde. Museu de História Natural, Universidade Estadual de Campinas (ZUEC 11507, adult male) and Museu de História Natural Capão da Imbuia, Curitiba (MHNCI 3243, adult male). Verified by Ariovaldo A. Giaretta. Original distribution was given as central and north Brazil, the chaco of Paraguay and Argentina, Amazon Basin, upper Orinoco Basin, Guianas, northern Colombia, and Trinidad (Frost 1995, Amphibian Species of the World. Version 2/95. Electronic manuscript, Herpetologists' League). First record for the state of Paraná; extends distribution to southern Brazil. Specimens were found calling in pond in an open area.

Submitted by **PAULO SÉRGIO BERNARDE**, Curso de Pós-Graduação em Zoologia, Departamento de Zoologia, Universidade Federal do Paraná, CP 19020, 81531-990, Curitiba-PR, Brazil; e-mail: bernarde@garoupa.bio.ufpr.br.

PSEUDACRIS CLARKII (Spotted Chorus Frog). USA: TEXAS: HAMILTON CO: Hico City Park. 10 April 1987. Bobby J. Schat. TAIC 5927 (3 specimens). Verified by Steve A. Smith. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **MICHAEL JAMES McCOID**, Department of Biology, Campus Box 158, Texas A&M University, Kingsville, Texas 78363, USA.

RANA AREOLATA AREOLATA (Southern Crawfish Frog). USA: TEXAS: REFUGIO CO: 8.8 km E,& 24 km N Refugio (28°31'6"N, 97°11'43"W). 4 July 1998. James M. Mueller. TCWC 79735 (specimen in ethanol and tissues in Longmire's solution for DNA studies). Verified by James R. Dixon. Collected at 1215 h by hand in grassland prairie dominated by *Spartina spartinae* and *Paspalum* spp. growing on sandy loam soil. Specimen was observed in the open next to northern bobwhite (*Colinus virginianus*) nest one day following 3.5 cm of rain during an unusually dry summer. New county record; westward range extension of ca. 60 km (Dixon 1987, Amphibians and Reptiles of Texas, Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **JAMES M. MUELLER**, Department of Range, Wildlife, and Fisheries Management, Texas Tech University, Lubbock, Texas 79409, USA.

RANA CATESBEIANA (Bullfrog) USA: COLORADO: CHEYENNE CO: pond on Rush Creek ca. 1.0 mile east of Lincoln County line (N 38 40.301, W 103 10.000). 1 adult taken, 3 juveniles sighted. 25 June 1998. UNC-MNH 1281. Verified by Hobart M. Smith and David Chiszar. First county record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **THERESA CHILDERS**, **ENOCH BERGMAN**, **JERRY D. MANZER**, and **STEPHEN P. MACKESSY**, Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639, USA.

SYRRHOPHUS MARNOCKII (Cliff Chirping Frog). USA: TEXAS: BANDERA CO: Lost Maples State Natural Area, 8.0 rd km N Vanderpool on FM 187. 10 June 1998. John H. Malone. TCWC 79861–62. Verified by James R. Dixon. County record; fills distribution gap amongst Kendall, Kerr, Real, Medina, and Uvalde counties (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp; and Dixon 1996, Texas Herpetol. Soc. Spec. Publ. 2). Specimens were collected during a herpetofaunal inventory for the Texas Parks and Wildlife Department, June–August 1998. All specimens were collected under the authority of State Park Scientific Study Permit 32-98. *Syrrhophus marnockii* was found to be common throughout all canyonlands in the park.

Submitted by **JOHN H. MALONE**, Herpetological Independent Study Group, Texas A&M University, Department of Wildlife and Fisheries Sciences, College Station, Texas 77843, USA.

TESTUDINES

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle). USA: TEXAS: POLK CO: crossing Rt. 190, 0.5 km E Menard Creek bridge and 8.6 km E of city limits of Livingston. 30 January 1998. Robert R. Fleet. Adult male. Verified by Lee Fitzgerald. SFAVM color slides 4892a–c. County record. (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **ROBERT R. FLEET** and **FRED C. RAINWATER**, Department of Biology, Stephen F. Austin State University, Nacogdoches, Texas 75962, USA.

ERETMOCHELYS IMBRICATA (Hawksbill). USA: GEORGIA: CAMDEN CO: dead on beach north of Dungeness Crossing, Cumberland Island. 1 June 1998. Carol Ruckdeschel and C. Robert Shoop. Cumberland Island Museum 98.06.01.03. Verified by G. R. Zug. Adult female, 87.5 x 72 cm CCL x W. First specimen from Georgia, although range extends along the Atlantic coast to New England.

Submitted by **CAROL RUCKDESCHEL** and **C. ROBERT SHOOP**, Cumberland Island Museum, P.O. Box 796, St. Marys, Georgia 31558-0796, USA.

KINOSTERNON FLAVESCENS FLAVESCENS (Yellow Mud Turtle) USA: COLORADO: LINCOLN CO: AOR. Rt. 94, 5.2 mi W jct. County Road 43 (near a tributary of Rush Creek; N38 51.035, W103 22.228). 16 June 1998. UNC-MNH Photographs 28–29. Verified by Hobart M. Smith and David Chiszar. First County record (Livo et al. 1996, Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.). This specimen represents a range extension of ca. 65 miles NW from the closest known occurrence on the Arkansas River in Prowers County.

Submitted by **ENOCH BERGMAN**, **JERRY D. MANZER**, **THERESA CHILDERS**, and **STEPHEN P. MACKESSY**, Department of Biological Sciences, 501 20th Street, University of Northern Colorado, Greeley, Colorado 80639, USA.

KINOSTERNON SCORPIOIDES (Scorpion Mud Turtle). BRAZIL: RORAIMA: 4°10'45"N, 61°0'46"W, Km 681 on the Boa Vista-Pacaraima Road. 16 August 1997. William E. Magnusson. Photograph digitalized on CD-ROM deposited in the Reptile Collection of the Instituto Nacional de Pesquisas da Amazónia, Manaus, Brazil (Registration Number 1523). Verified by Richard C. Vogt. Species has been recorded from widespread localities in South America, but the only previous record from the state of Roraima is from the Serra de Lua, ca. 180 km south of our record (Cabrera and Colantonio 1997, J. Herpetol. 31:507–513).

Submitted by **WILLIAM E. MAGNUSSON**, **ALBERTINA P. LIMA**, and **MARIA CARMOZINA DE ARAÚJO**, Coordenação de Pesquisas em Ecologia, Instituto Nacional de Pesquisas da Amazónia, CP 478, 69011-970 Manaus AM, Brazil.

LEPIDOCHELYS OLIVACEA (Pacific Ridley). USA: ALASKA: near Ketchikan, (55°20'N, 131°35'W). June 1991. Dry carapace (81 cm x 60 cm) on beach, confiscated by National Marine Fisheries Service (NMFS) Special Agent Jeff Passer, Sitka, Alaska. Verified by Karen L. Eckert. Carapace, photographs, and NMFS enforcement documents in herpetological collection of NMFS Auke Bay Laboratory (AB92-22), Juneau, Alaska. Other skeletal and soft parts missing at time of discovery, although some skin was still attached to the bones. It is not possible to determine the time or place of death, which may have occurred in Alaska or the carcass may have reached Alaska as flotsam from more southern regions of the eastern North Pacific Ocean. Alaska marine conditions during the late winter and spring of 1991 were slightly cooler than average.

This is the first confirmed *Lepidochelys olivacea* from Alaska and the northernmost record to date. Ketchikan is 913 km north of the previous northern record, Copalis Beach, Washington (Richardson 1997, Washington State Status Report, Olive Ridley Sea Turtle. Washington Dept. Fish & Wildlife, Olympia. 14 pp.). *Lepidochelys olivacea* is the fourth species of marine turtle recorded from Alaska waters.

Submitted by **BRUCE L. WING**, Auke Bay Laboratory, 11305 Glacier Highway, Juneau, Alaska 99801, USA, and **ROBERT PARKER HODGE**, 181 Raft Island, Gig Harbor, Washington 98335, USA.

LACERTILIA

ANOLIS BARKERI (Barker's Anole). MÉXICO: TABASCO: MUNICIPALITY OF HUIMANGUILLO, ca. 1 km W of Carlos A. Madrazo, dirt road to Pedregal River near the border of Veracruz (17°23'N, 93°40'W), 245 m. 25 March 1998. Fernando Mendoza Quijano and Ma. de los Angeles Sánchez Arriola. Colección Nacional de Anfibios y Reptiles, Instituto de Biología, UNAM, IBH 12396 (formerly TP 062, SVL = 45.8 mm, TL = 81.7 mm), a subadult male found in riparian vegetation. First record for state; extends range ca. 56 km NW from the closest known locality in Cascajal, Veracruz (Schmidt 1939, Publ. Field. Mus. Nat. Hist., Zool. Ser. 24[2]:7–9); MUNICIPALITY OF HUIMANGUILLO, ca. 3 km E of Carlos A. Madrazo (17°22'N, 93°39'W), 320 m. 26 March 1998. Fernando Mendoza Quijano. IBH 12397 (formerly TP 065, SVL = 79.2 mm, TL = 116 mm), an adult male found in cloud forest in ravine with small waterfall on leaf litter. Extends distribution at least some 57 km NW from former records in Cascajal, Veracruz. Both specimens verified by Adrian Nieto Montes de Oca.

Submitted by **VÍCTOR HUGO REYNOSO ROSALES, CLAUDIA S. VALDESPINO TORRES**, Colección Nacional de Anfibios y Reptiles, IBUNAM, Apartado Postal 70-153, C.P. 04510, México, Distrito Federal, México, and **FERNANDO MENDOZA QUIJANO**, Instituto Tecnológico Agropecuario No. 6, km 5.5 Carr. Huejutla-Chalahuiyapa, Apartado Postal 94, C.P. 43000, Huejutla de Reyes, Hidalgo, México.

ANOLIS CAROLINENSIS (Green Anole). USA: TEXAS: BANDERA CO: Lost Maples State Natural Area, 8.0 rd km N Vanderpool on FM 187. 4 June 1998. John H. Malone. TCWC 79908. Verified by James R. Dixon. County record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp; and Dixon 1996, Texas Herpetol. Soc. Spec. Publ. 2). Specimen was collected during a herpetofaunal inventory for the Texas Parks and Wildlife Department, June–August 1998. All specimens were collected under the authority of State Park Scientific Study Permit 32-98.

Submitted by **JOHN H. MALONE**, Herpetological Independent Study Group, Texas A&M University, Department of Wildlife and Fisheries Sciences, College Station, Texas 77843, USA, and **WAYNE DAVIS**, Lost Maples State Natural Area, HCO1, Box 156, Vanderpool, Texas 78885, USA.

EUMECES LATICEPS (Broadhead Skink). USA: FLORIDA: HERNANDO CO: Chassahowitzka Wildlife Management Area, 28°38'33"N, 82°35'28"W. 10 July 1995. Kristin N. Wood. UF 109402. Verified by David L. Auth. New county record (Ashton and Ashton 1991, Handbook of Reptiles and Amphibians of Florida. Part 2: Lizards, Turtles and Crocodilians. Revised edition. Windward Publ., Miami. 191 pp.). Collected from a funnel trap in a hydric hammock.

Submitted by **KRISTIN N. WOOD**, Florida Game and Fresh Water Fish Commission, 23212 Lake Lindsey Road, Brooksville, Florida 34601, USA.

HEMIDACTYLUS MABOUIA (Tropical Gecko). USA: FLORIDA: BREVARD CO: I-95 between SR 406 and 405 in Titusville. 13 August 1998. Noah Anderson, Todd Campbell, Bridget Quinn. Louisiana State University Museum of Natural Science (LSU 80027–28). Verified by Brian Crother. New county record; extends range ca. 190 km NE of Glades County. One adult male (SVL = 64 mm) and one gravid female (SVL = 61 mm) collected from hotel walls. Sympatric with *H. turcicus*. Also, *H. garnotii* found in Titusville, but not present with either *H. turcicus* or *H. mabouia* (Meshaka et al. 1994, Herpetol. Rev. 25:165).

Submitted by **CHARLES D. CRISCIONE** and **NOAH J. ANDERSON**, Department of Biological Sciences, Southeastern Louisiana University, Hammond, Louisiana 70402-10736, USA, **TODD CAMPBELL**, Department of Ecology and Evolutionary Biology, University of Tennessee, 569 Dabney Hall, Knoxville, Tennessee 37996-1610, USA, and **BRIDGET QUINN**, 356 West Ogden Street, Girardville, Pennsylvania 17935, USA.

HEMIDACTYLUS TURCICUS (Mediterranean Gecko). USA: TEXAS: BANDERA CO: Lost Maples State Natural Area, 8.0 rd km N Vanderpool on FM 187. 4 June 1998. John H. Malone. TCWC 79911. Verified by James R. Dixon. County record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp; and Dixon 1996, Texas Herpetol. Soc. Spec. Publ. 2). Specimen was collected during a herpetofaunal inventory for the Texas Parks and Wildlife Department, June–August 1998. All specimens were collected under the authority of State Park Scientific Study Permit 32-98. *Hemidactylus turcicus* was found to be established at the campground bathroom and park maintenance area.

Submitted by **JOHN H. MALONE**, Herpetological Independent Study Group, Texas A&M University, Department of Wildlife and Fisheries Sciences, College Station, Texas 77843, USA.

MABUYA HEATHI. BRAZIL: BAHIA: ABROLHOS ARCHIPELAGO (17°58'S, 38°42'W), Sueste Island. 8 March 1995. G. F. Dutra and T. M. Guerra. Museu do Rio de Janeiro (MNRJ 6652–54); 13 April 1997. G. F. Dutra and D. Vrcibradic. MNRJ 6655–59; 15 April 1997. D. Vrcibradic. MNRJ 6660–62; Siriba Island. 17 April 1997. D. Vrcibradic. MNRJ 6663–64. All verified by Paulo E. Vanzolini. Also observed (but not collected) on Redonda Island by G. F. Dutra in 1995. The species is relatively abundant on the archipelago of Abrolhos (except on Santa Barbara, the largest of the four islands, where it is apparently absent), which lies ca. 70 km from the nearest continental coastline. According to previous published data on the distribution of this lizard (Vanzolini et al. 1980, Répteis das Caatingas. Academia Brasileira de Ciencias, Rio de Janeiro. 161 pp.; Peters and Donoso-Barros 1986, Catalogue of Neotropical Squamata. Part II. Lizards and Amphisbaenians. Bull. U.S. Natl. Mus. 297.293 pp.), it ranged from the state of Ceará (type locality Fortaleza, 3°48'S, 38°38'W) to near Salvador (12°50'S, 38°25'W) in Bahia. This is the first published insular record for the species.

Submitted by **GUILHERME FRAGA DUTRA** and **DAVOR VRCIBRADIC**, Pós-Graduação em Ecologia, Departamento de Zoologia, C. P. 6109, Universidade Estadual de Campinas, 13081-970 Campinas, São Paulo, Brazil. *Corresponding address for DV:* Setor de Ecologia, Instituto de Biologia, Universidade do Estado do Rio de Janeiro, Rua S. Francisco Xavier, 524, Maracana, 20550-011, Rio de Janeiro, Rio de Janeiro, Brazil.

THAMNOPHIS SIRTALIS (Common Garter Snake). USA: NEW MEXICO: CHAVES CO: Bitter Lake National Wildlife Refuge, funnel trap on gravel rd between Units 3 & 5; 16.5 air km NE Roswell (jct U.S. Rts. 380 & 285); NE1/4 Sec 9, T10S, R25E, 33°27'38.8" N 104°23'58.4" W. 25 April 1998. Gordon L. Warrick. University of New Mexico Museum of Southwestern Biology (MSB 61103). Verified by D. S. Sias. MSB 61103 is an adult male 365 mm SVL, 120 mm TL. On 24 May 1998 a gravid female 800 mm SVL, 190 mm TL was captured at the same site, photographed, and released (KU Color Slide11257–58). The specimens reported herein are the first to be collected outside of the Rio Grande drainage in New Mexico since those reported by Bundy (1951, Copeia 1951:314) and specimens reported to CWP as Ohio University Vertebrate Collection (OUCV 2640–41) collected during July 1950. Given that specimens had not been

discovered in this area for almost 50 years, the population of *T. sirtalis* in the Pecos River drainage was presumed likely extirpated (Degenhardt et al. 1996, Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA, and **GORDON L. WARRICK** and **WILLIAM R. RADKE**, Bitter Lake National Wildlife Refuge, P.O. Box 7, Roswell, New Mexico 88202, USA.

Distribution Records and Life History Notes for Amphibians and Reptiles in Belize

The distributions of amphibians and reptiles in Belize have recently been reviewed and summarized in Lee (1996). We herein report additional records and life history data collected from 1993 to 1997. Records were determined based on comparisons with range maps and locality data presented in Lee (1996). Place names correspond to topographical maps issued by the Ordnance Survey, Southampton, England and obtained from the Department of Lands and Surveys, Belmopan, Belize. Voucher specimens or photographs are deposited in the Campbell Museum (CUSC), Clemson University, Clemson, South Carolina, USA.

Bufo marinus (Marine Toad). TURNEFFE ATOLL: Calabash Cay (17°17'N; 87°49'W). 25 February 1997. Steven G. Platt and Thomas R. Rainwater. Verified by Jacob A. Marlin. CUSC 1569. First record for Turneffe Atoll. Not previously reported from any offshore habitat in Belize.

Chelydra serpentina (Common Snapping Turtle). TOLEDO DISTRICT: Agua Caliente Swamp, ca. 2 km N Laguna Village (16°10'N; 88°58'W). 11 June 1997. Steven G. Platt and Thomas R. Rainwater. Verified by Jacob A. Marlin. CUSC 1438. Carapace (length = 39.0 cm) of an adult recently killed by fishermen. Previously recorded from only three sites in Belize, all within 20 km of Agua Caliente Swamp. According to locals *C. serpentina* is common in the swamp and regularly harvested for food. Hunting Cay in the Sapodilla Cay Group (16°07'N; 88°16'W). 7 December 1997. Captured by Belize Defense Force personnel and deposited in the Belize Zoo. Voucher photograph. Verified by Anthony Garel. CUSC 1559. First record from any offshore island in Belize. The nearest populations are on the mainland, ca. 60 km W of Hunting Cay. It is likely the turtle was transported to the island by humans. Hunting Cay is a small (ca. 0.5 km^2) mangrove island with no available freshwater habitat, and is unlikely to support a resident population of *C. serpentina*.

Claudius angustatus (Narrow-bridged Mud Turtle). ORANGE WALK DISTRICT: 3.4 km SE San Felipe Village on San Felipe to Indian Church Road (17°52'N; 88°45'W). 14 August 1993. Steven G. Platt. Verified by William E. Snyder. Voucher photograph. CUSC 1558. District record. Extends range ca. 50 km NE.

Crocodylus acutus (American Crocodile). AMBERGRIS CAY: San Pedro Lagoon, ca. 1.5 km N San Pedro (17°55'N; 87°58'W). 2 October 1996. Steven G. Platt. Verified by Jacob A. Marlin. Voucher photograph. CUSC 1468. Western shoreline, ca. 20 km NW of San Pedro (17°58'N; 87°58'W). 1 November 1996. Steven G. Platt. Verified by Jacob A. Marlin. Voucher photograph. CUSC 1474. Laguna Cantena, ca. 30 km NE of San Pedro (18°09'N; 87°51'W). 28 May 1997. Steven G. Platt. Verified by Jacob A. Marlin. Voucher photograph. CUSC 1476. BELIZE DISTRICT: Belize City, University College of Belize Campus, ca. 2 km E Northern Highway (17°30'N; 88°12'W). 14 January 1997. Steven G. Platt. Verified by Jacob A. Marlin. Voucher photograph. CUSC 1475. Cay Caulker, mangrove swamp adjacent to municipal airstrip, ca. 22 km NE Belize City (17°46'N; 88°02'W). 24 April 1997. Steven G. Platt. Verified by Jacob A. Marlin. Voucher photograph. CUSC 1449. Hicks Cay, northern shoreline, ca. 22 km N Belize City (17°41'N; 88°09'W). 19 July 1996. Steven G. Platt. Verified by Jacob A. Marlin. Voucher photograph. CUSC 1471. Long Cay, interior mangrove swamp, ca. 20 km NE Belize City (17°38'N; 88°04'W). 19 February 1997. Steven G. Platt and Thomas R. Rainwater. Verified by Travis Crabtree. Voucher photograph. CUSC 1472. Maps Cay, ca. 12 km W Belize City (17°30'N; 88°05'W). 27 January 1997. Steven G. Platt. Verified by Jacob A. Marlin. Voucher photograph. CUSC 1470. Northern River Lagoon, ca. 10 km E Maskall Village (17°53'N; 88°13'W). 24 October 1997. Steven G. Platt and Steven Brewer. Verified by Jacob A. Marlin. Voucher photograph. CUSC 1447. Western Lagoon, ca. 6 km NW Gales Point Village (17°16'N; 88°20'W). 18 September 1997. Steven G. Platt. Verified by Jacob A. Marlin. Voucher photograph. CUSC 1469.

The distribution of *C. acutus* in Belize has long been uncertain owing to confusion with the sympatric Morelet's crocodile (*C. moreletii*), and the only previous records were from the Turneffe Atoll (Lee 1996). Our records extend the distribution north ca. 100 km to the Mexican border, and south ca. 120 km to Toledo District. Within this range *C. acutus* is expected on most offshore cays, but appears rare and confined to scattered localities on the coastal mainland. We found no evidence for the occurrence of *C. acutus* in any inland, freshwater habitats (Platt 1996).

Coniophanes schmidti (Schmidt's Striped Snake). ORANGE WALK DISTRICT: Lamanai Outpost Lodge, Indian Church Village (17°46'N; 88°40'W). 28 December 1997. Hong Liu and Steven G. Platt. Verified by Julian C. Lee. CUSC 1564. Previously known in Belize from two specimens collected in the Mountain Pine Ridge, Cayo District. This specimen represents a District record and extends the range ca. 70 km NE of the Mountain Pine Ridge. An intact bird egg was found in the stomach.

Crotalus durissus (Neotropical Rattlesnake). TOLEDO DISTRICT: Southern Highway, ca. 16 km NE Medina Bank Village (16°27'N; 88°37'W). 17 April 1997. Steven G. Platt. Verified by Jacob A. Marlin. CUSC 1440. Logging road ca. 7.1 km SE of Bladen River Bridge, Southern Highway (16°24'N; 88°38'W). 19 April 1997. Steven G. Platt. Verified by Jacob A. Marlin. CUSC 1441. Both specimens were DOR in extensive coastal pine savannas. A partially digested rodent (probably *Sigmodon hispidus*) was found in the stomach of CUSC 1440. These District records are the southernmost for Belize, and constitute a range extension of ca. 70 km S from populations in the Mountain Pine Ridge, Cayo District. BELIZE DISTRICT: ca. 5 km N of Democracia Village (17°22'N; 88°34'W). 21 October 1997. Steven G. Platt. Verified by Jacob A. Marlin. CUSC 1452.

Found in a recently (April 1997) burned pine savanna approximately 1.0 m from an armadillo burrow. Western Highway, ca. 6.4 km W of Hattieville (17°25'N; 88°24'W). 22 August 1997. Steven G. Platt. Verified by Jacob A. Marlin. CUSC 1450. Found in wet coastal savanna dominated by sedges and palms (*Paurotis* sp.). These specimens represent District records and constitute a range extension of ca. 60 km NE from populations in the Mountain Pine Ridge. ORANGE WALK DISTRICT: Lamanai Outpost Lodge, Indian Church Village (17°46'N; 88°40'W). 2 August 1997. Thomas R. Rainwater. Verified by Jacob A. Marlin. CUSC 1450. Extends distribution ca. 30 km SE of August Pine Ridge Village, the previous southernmost record outside of the Mountain Pine Ridge. The habitat at this site consists of second-growth hardwood forest and milpas in various stages of abandonment. Pine savanna is absent, contradicting Fugler's (1960) statement that *C. durissus* in Belize is restricted to savanna habitats. Although Lee (1996) speculated that *Bothrops asper* may competitively exclude *C. durissus* from forested habitats, both species occur at this locality (S. Platt and T. Rainwater, pers. obs.).

Ctenosaura similis (Spiny-tailed Iguana). TURNEFFE ATOLL: beach on Northern Cay (17°29'N; 87°47'W). 4 April 1997. Steven G. Platt and Thomas R. Rainwater. Verified by Jacob A. Marlin. CUSC 1448. First record for the Turneffe Atoll. Common on beach ridges and littoral forest throughout the atoll. Nearest populations are 40 km SE on Half Moon Cay, Lighthouse Atoll.

Leptophis mexicanus hoeversi (Mexican Green Tree Snake). TURNEFFE ATOLL: Calabash Cay (17°17'N; 87°49'W). 15 June 1995. Steven G. Platt. Verified by Jacob A. Marlin. CUSC 1546. Northern Cay (17°29'N; 87°47'W). 25 June 1997. Steven G. Platt. Verified by Jacob A. Marlin. CUSC 1435. *L. mexicanus* was previously reported in the Turneffe Atoll only from Big Cay Bokel (Henderson 1976). We found *L. mexicanus* common in littoral forests throughout the atoll, and both blue (1435) and green (1546) morphs were encountered. The blue morph has not been previously reported, and these individuals exhibit a bright blue dorsum devoid of any markings. Although mistakenly labeled as *Leptophis ahaetulla*, a photograph of both *L. mexicanus hoeversi* morphs collected by SGP on Calabash Cay appears in Garel and Matola (1996). Snakes were observed feeding on *Anolis sagrei*, which are abundant in the atoll.

Tantillita canula (Yucatan Dwarf Short-tailed Snake). ORANGE WALK DISTRICT: Lamanai Outpost Lodge, Indian Church Village (17°46'N; 88°40'W). 16 July 1997. Thomas R. Rainwater. Verified by Julian C. Lee. CUSC 1556. Snake found dead after application of pesticide to ornamental plants. This represents the fourth specimen from Belize. Two specimens were previously collected at Lamanai Archaeological Site, ca. 2 km N of Lamanai Outpost Lodge (Lee 1996).

Thamnophis marcianus (Checkered Garter Snake). ORANGE WALK DISTRICT: Lamanai Outpost Lodge, Indian Church Village (17°46'N; 88°40'W). 25 September 1997. Thomas R. Rainwater. Verified by Jacob A. Marlin. CUSC 1453. District record extending distribution ca. 30 km NW of previous range limit in the Belize District.

Acknowledgments.—Julian C. Lee and John B. Thorbjarnarson are thanked for reviewing early drafts of this manuscript. The assistance of Julian C. Lee, Jacob A. Marlin, Anthony Garel, Travis Crabtree, and William E. Snyder in verifying our identifications was most appreciated. We are grateful to Raphael Manzanero and Emil Cano, Conservation Division, Forest Department, Belmopan for issuing the necessary collecting, research, and export permits. Fieldwork in the Turneffe Atoll was assisted by Coral Cay Conservation and University College of Belize. Further assistance was provided by Hong Liu, Brenda Salgado, Mark and Monique Howells and Lamanai Outpost Lodge, Richard and Carol Foster, William Hasse, Matthew Miller, Bruce and Carolyn Miller, Richard Montanucci, and John Scavo. Stanlee Miller of the Campbell Museum assisted in the preparation and deposition of voucher material. Support for SGP was provided by Wildlife Conservation Society. TRR was supported by Lamanai Field Research Center.

Distributional Records for Louisiana Amphibians

JEFF BOUNDY
Louisiana Department of Wildlife and Fisheries, P.O. Box 98,000
Baton Rouge, Louisiana 70898-9000, USA
e-mail: boundy_jj@wlf.la.state.us

The following Louisiana State University Museum of Natural Science (LSUMZ) specimens represent new parish records for Louisiana. Pertinence of records are based on distributional data provided by Dundee and Rossman (1989). Identification of specimens was verified by Douglas Rossman.

Ambystoma maculatum (Spotted Salamander). Richland Parish: 0.7 mi NE Rayville. Larry Wilson. LSUMZ 42531. 11 September 1965. Sabine Parish: Bayou Toro at LA 392. Jack Deshotels, Philip St. Romain, Mark Staton. LSUMZ 60050. 16 August 1973.

Ambystoma opacum (Marbled Salamander). Concordia Parish: 1 mi S Clayton. Larry Wilson, A. Romano. LSUMZ 25211–25213. 2 March 1965. St. Martin Parish: 4 mi N of I-10 on Whiskey Bay exit. Mike Kirton. LSUMZ 60312–13. 1 February 1975. West Baton Rouge Parish: 7–9 mi W Port Allen. D. May, E. Armstrong, Lawrence Binford, Burt Monroe, Jr. LSUMZ 6735–38. 14–25 February 1962. 6 mi N Port Allen. G. Schaefer. LSUMZ 17538. 4 April 1964. 6 mi E Rosedale. James Hebrard, John O'Neill. LSUMZ 17907, 18609. 22 February 1967.

Ambystoma talpoideum (Mole Salamander). Ascension Parish: 2.5 mi E, 0.8 mi S of Galvez. LSUMZ 59523. F. Marabella. December 1997.

Ambystoma texanum (Smallmouth Salamander). Iberia Parish: between Loreauville and Lake Fausse Pointe. Todd Lewis. LSUMZ 57534–35. March 1996. Vernon Parish: 1.9 mi N jct Louisiana 464 and Louisiana 111. Larry Wilson. LSUMZ 42240–41. 19 February 1966.

Amphiuma means (Two-toed Amphiuma). East Baton Rouge Parish: Camp Istrouma, Indian Mound. Jeff Boundy, Steve Shively. LSUMZ 59692–93. 17–19 June 1998.

Amphiuma tridactylum (Three-toed Amphiuma). Ascension Parish: 2.5 mi E, 0.8 mi S of Galvez. LSUMZ 59528. J. Boundy. 27 March 1998.

Desmognathus conanti (Spotted Dusky Salamander). Red River Parish: 10 mi NNE Coushatta on Louisiana 788. Larry Wilson. LSUMZ 28084. 18 December 1966.

Eurycea quadridigita (Dwarf Salamander). Iberville Parish: 6 mi WNW Rosedale. Larry Wilson. LSUMZ 51816. 31 December 1964.

Hemidactylium scutatum (Four-toed Salamander). Ascension Parish: 2.5 mi E, 0.8 mi S of Galvez. LSUMZ 59524. F. Marabella and J. Faggard. 17 March 1998.

Necturus maculosus (Common Mudpuppy). Evangeline Parish: 0.5 mi N Dossman at Bayou Cocodrie. Howard Dupre. LSUMZ 62954. 8 January 1976.

Notophthalmus viridescens (Eastern Newt). Madison Parish: 0.2 mi E Indian Lake on Spur Louisiana 577. LSUMZ 23947. 3.7 mi W U.S. 65 on Spur Louisiana 577. R. Van den Bold. LSUMZ 37785. 24 April 1971.

Plethodon kisatchie (Kisatchie Slimy Salamander). Catahoula Parish: tributary of Sugar Creek, T10N, R5E, NW quarter S21. Steve Shively. LSUMZ 58297. 19 March 1997.

Plethodon mississippi (Mississippi Slimy Salamander). Ascension Parish: 2.5 mi E, 0.8 mi S Galvez. Jeff Boundy, Frank Marabella. LSUMZ 58248. 18 February 1997. LSUMZ 58256. Frank Marabella. January 1997.

Siren intermedia (Lesser Siren). Ascension Parish: 2.5 mi E, 0.8 mi S Galvez. Frank Marabella. LSUMZ 58253. 16 February 1997. Iberville Parish: Nicholson Drive, ca. 11 mi SE Baton Rouge. Robert Claire. LSUMZ 37785. May 1979.

Eleutherodactylus planirostris (Greenhouse Frog). St. Bernard Parish: Louisiana 300, 1.5 mi E Louisiana 46 at Reggio. Steve Karsen. LSUMZ 59096. 1 November 1997. St. John the Baptist Parish: 100 Vicknair Place, east side of LaPlace. Steve Karsen, Jeff Boundy. LSUMZ 58208. 3 February 1997.

Gastrophryne carolinensis (Eastern Narrowmouth Toad). East Carroll Parish: Transylvania, Mississippi River levee. Douglas Rossman. LSUMZ 23952–54. 24 April 1971.

Hyla avivoca (Bird-voiced Treefrog). Tensas Parish: Tensas Bayou at Fool River. Steve Shively. LSUMZ 57192–95. 27 July 1995.

Hyla cinerea (Green Treefrog). West Baton Rouge Parish: 6 mi W Port Allen. G. Schaefer. LSUMZ 15481–82. 4 April 1964. Rosedale Road. Larry Wilson, A. Romano. LSUMZ 15483, 51575. 7 April 1964. Louisiana 415 between Louisiana 76 and US 190. Larry Wilson. LSUMZ 41405. 2 March 1966. Rosedale Road. Larry Wilson. LSUMZ 41985. 2 March 1966. 5.0 mi S Port Allen, 0.5 mi W of Louisiana 1. Jeff Wilkinson. LSUMZ 49491–93. 14 February 1990. 4 mi E Rosedale. Edmund Keiser. LSUMZ 66316. 26 April 1965. Louisiana 76, near parish line. Edmund Keiser. LSUMZ 66325. 26 April 1965.

Hyla gratiosa (Barking Treefrog). West Feliciana Parish: 0.7 mi W Louisiana 66 on Highland Road, Sec. 89. Randy Vaeth, Jim McLean. LSUMZ 36929. 23 June 1978.

Pseudacris feriarum (Upland Chorus Frog). Ascension Parish: 2 mi E Geismar. E. Hastings. LSUMZ 6134. 15 February 1953.

Acknowledgments.—Thanks are due Harold Dundee for investigating several questionable records in the Tulane University collection.

e-mail: M.Hero@eas.gu.edu.au

This comprehensive book is an impressive collection of individual papers covering the broad scope of current research (all papers include research post 1990) related to amphibian declines in Canada. It was a pleasure to read the book as the breadth of content and methodologies used gives the reader a complete overview of the extent of research involved in trying to understand the current status of Canadian amphibians. Unfortunately, this made me realize that the work over the past seven years is only the tip of the iceberg and an enormous amount of research is necessary to resolve this complex problem, involving many species and many potential causes (known and unknown).

As mentioned in the foreword, this book is a collection of papers on research developed and presented in isolation. Consequently, it is not a coordinated effort aimed at documenting and understanding amphibian declines at a national scale. This problem is also evident in other countries and may result partly from the geographical isolation of research institutes. Research should reflect a communal concern to resolve a national problem and should be coordinated at either a species or subject level. Wildlife managers should focus on determining the current status of populations, and research teams on resolving specific hypotheses to explain observed declines (i.e., natural population dynamics, disease, UV, radiation etc.) coordinated at a species level (rather than political boundaries). The message from this book is clear, the problem is immense and scientists must work together to examine specific hypotheses and replicate research among species and across latitudinal boundaries.

The first chapter presents a good example of the broad surveys needed to assess the factors influencing the distribution and abundance of amphibians. This study allows us to evaluate the biological factors determining species distributions (i.e., the presence/absence of fish), the stochastic nature of species distributions and, when replicated over many years, allows assessment of the status of species on a regional scale. This is exactly what is urgently needed to assess amphibian populations throughout the world. The following chapters (2–6) present intensive studies on the population dynamics of particular species at given localities, providing a basis for understanding amphibian population dynamics at the population level. Chapter 7 presents a fine example of metapopulation dynamics, and dispersal characteristics among populations. This information is crucial for managing species in fragmented landscapes. The broad survey result, presented in Chapter 8, provides a good example of using calling survey data (albeit for a single species) for rapid assessment of population numbers compared with historical data to determine population declines.

The potential role of conservation genetics is presented in Chapters 9, 10 and 28. Their application is clearly lacking from research to date and field ecologists should collaborate with

geneticists (for example, providing the toe-clips from population studies) to utilize the advantages of population genetics. In Chapters 11 (three papers), 12, 13 and 14, a variety of methods are used to assess the status of amphibian populations in particular provinces. Calling surveys are used to identify species-habitat relationships in agricultural landscapes in Chapter 15, and a good evaluation of the technique is presented in Chapter 16. The use of artificial covers for assessing salamander populations is evaluated in Chapters 17 and 18 and a method for sub-sampling aquatic frogs is presented in Chapter 19 (see discussion below). Potential impacts of forestry activities are described in Chapters 20 and 21, followed by an assessment of the potential impacts of global warming and increased UV radiation on amphibian populations in Chapter 22. The potential changes in amphibian populations at four ponds resulting from changes in water acidity is presented in Chapter 23. Experimental analyses of herbicides and pesticides on egg and larval survival are assessed in Chapter 24, followed by an assessment of agriculture on amphibian deformities (potentially related to herbicide/pesticide residues) in Chapter 25. The role of disease in amphibian declines is well reviewed in Chapter 26. Chapter 27 presents an alternative view on larval surveys and the use of chemical control for introduced species.

The final chapter provides a good overview of the problems associated with assessing amphibian populations and the important distinction between "population size" and "population numbers". The stochastic nature of amphibian populations makes the former difficult to interpret without long term data. The latter (as presented in Chapter 1) is more appropriate for rapid assessment of population status. Finally, a summary of the current status of each species (within each province) is presented in Appendix 1, a suitable basis for management and conservation agencies. The declines are generally attributed to direct anthropological causes yet declines are prevalent in western Canada where human populations are less concentrated.

The large number of authors with a wide range of experience make this book a significant contribution to our understanding of amphibian biology. Many provide excellent examples of methodology and experimental design, however the range of experience of the authors results in some papers lacking rigorous scientific integrity. As for any journal article the reader must consider the experimental design, the results obtained, and the limits on the conclusions reached. In several cases substantial results were overlooked in the discussion, or conclusions are presented without data to support them. One frequent limitation in experimental design results from surveying less than five populations (sometimes within a single waterbody) that may not represent broad patterns for a species. This may result from the limitations imposed by working with endangered species for which only a few sites may be available, but should be avoided whenever possible.

Surprisingly, this book contains little evidence of frog declines in Canada (although see Appendix 1 for species accounts) and no evidence of declines in any of the salamanders. Predicted causes for amphibian declines result from a complex suite of potential (habitat modification, pesticides and herbicide pollution, etc.), postulated (global climate change, disease, acid rain, etc.), and unexplained causes (Chapter 8).

These potential causes are most likely acting independently (although several factors may be acting at the same time) upon each species in each province. Observed declines are associated with habitat destruction, fragmentation and degradation (Appendix 1, however, see Chapter 8). Fortunately, appropriate management actions can be instigated (e.g., forestry regulations, planning urban and agricultural expansion) as political action is clearly the only way to mitigate these anthropogenic effects. The predicted influence of global warming and increased UV radiation on amphibian assemblages once again reminds us of the need for all countries to ensure they are doing everything possible to reduce the local emissions responsible for changing the global environment.

For biologists working on unexplained declines in relatively pristine areas (e.g., eastern Australia, the Rocky Mountains of North America, Central America, and the Andes or Atlantic Forest regions of South America) this volume provides little insight into determining the cause of these declines. Contrary to the conclusion of this book, I believe the fundamental cause of these declines may still be global, however I agree that the primary way of determining the cause of declines will ultimately depend on research at the local scale.

Reflections on several important points raised in this volume include:

1) The sheer amount of research needed is a daunting task and priorities based on rapid assessment are urgently required. A good initiative is presented by Kristiina Ovaska (Chapter 22). However, in her model, the conservation status for each species was included as an independent variable. To create a predictive model that will identify which species are susceptible to global change, current conservation status could be used as the dependent variable. The resulting model would identify the species characteristics which are significantly associated with population declines, also a list of species predicted to be most susceptible to the proposed global changes could be generated.

2) Large-scale surveys are required to document population declines (e.g., Chapters 1, 8, 12, 15, 16, 17, 18 and 28), however, surveys were often restricted to individual species or habitats (water bodies) and/or provincial-political boundaries. Determining species priorities will greatly assist this forbidding task.

3) The variety of methodologies presented provides useful techniques but each contains inherent biases that must be considered in their interpretation and hence application. Adequate surveying often requires species-specific survey techniques. For example, the survey methods in Chapter 1 only sampled species that reproduce in permanent ponds, calling surveys on road transects (Chapters 14–16) only detect vocal species from ponds and not stream-dwelling species, and the use of artificial covers is only effective for some species of salamanders and not others (Chapters 17 and 18). The transect survey method in Chapter 19 may be effective, however no comparison is made with alternative methods. Research on appropriate methodologies would be more productive if compared with alternative methods either in the same place at the same time, or with published results from other studies (e.g., Chapter 16). Alternatively, a single methodology could have been used to compare their efficiency at answering certain ecological questions.

4) Broad scale surveys are urgently required to determine the current status of all species at the "population number" scale (e.g., Chapter 1). Intensive mark-recapture studies provide important baseline data on how individual populations fluctuate (Chapters 2–6), however, they are of limited benefit as they rarely differentiate between immigration, emigration, birth, and mortality. The labor-intensive fieldwork required obtaining this detailed information on population dynamics limits the scope of these studies to a few sub-populations (at the pond or stream level). Sites of high abundance are usually chosen, and without adequate replication across the distribution of the species, these studies do not provide information at the species level. For example, the dynamics of a sub-population will not represent a species if it is a "sink" population. Subsequently, intensive mark and recapture

studies contribute little to our understanding of population declines. However as stated in the editor's final chapter, they will provide valuable information on the dynamics of amphibian populations that may be extremely useful in identifying the cause of a population decline.

Finally, I cannot agree with the conclusions of Chapter 27, supported in the final chapter by Green, suggesting that larval surveys are "largely inapplicable to monitoring the health or persistence of a population." First, there are no data presented to support this contention. The complex life-history of amphibians makes it difficult to pinpoint the most important life stage for population regulation (e.g., Chapter 5). Clearly combined survival at all stages (embryo, larval, juvenile, and adult) influence population size. Studies on population dynamics and regulation must consider all life-history stages.

Several papers presented in this book demonstrate the value of larval surveys (Chapter 1). In the study by Green (Chapter 5), the number of calling males in any year could not be related to the number in the previous year, suggesting that the adult population is regulated by larval recruitment. Unfortunately, larval abundance was not monitored in that study and the role of larval recruitment as a crucial stage in the life-history of this species could not be assessed. Clearly, to understand the "population demographics" of any amphibian species, both larval and adult populations must be considered.

Regarding the question of "population number" the presence of larvae represents the likelihood of reproductive success and hence would be a better indicator of population persistence than the presence of adults. While this may vary for a few ephemeral pond-breeding species (where larval mortality may reach 100 %), most species in Canada appear to breed in more permanent water bodies and larvae are present for extensive time periods (some overwintering). The results of Chapter 7 also demonstrated the value of larval surveys. In that study the presence of adults did not reflect reproductive success as only one pond produced metamorphs (i.e., source vs sink populations). This study demonstrates that the mobility of adults makes adult population estimates difficult to interpret (as mentioned above). Furthermore, tadpole surveys can be useful when searching for remaining populations of species that have significantly declined, particularly for species with a cryptic adult life stage (e.g., *Taudactylus* species in Australia).

Monitoring both larval and adult stages allows us to assess the relative importance of any water body to the success/survival of the species (Chapter 1). For "population number" long-term monitoring of any life-history stage can be surveyed and all are suitable as indices of population status. Larval surveys are often much easier to employ, and are not subject to the immediate climatic effects that limit the activity of adults to certain conditions or particular times of year.

In summary, the book is a credit to the editor, it has an ample scattering of black and white photos that allow overseas readers to visualize the species they are reading about and there are few typographical errors. Reading the book in its entirety provokes constructive thoughts on this global phenomenon and clearly provides insight into appropriate methodologies and direction for future research. The reasonable price and invaluable contents of this book make it a must for anyone interested in amphibian declines.

Amphibians of Iran, by M. Baloutch and H. G. Kami. 1995. Tehran University Publications (no. 2250), Tehran. Softcover, 177 pp. In Farsi (Persian), with Latin taxonomic names and authors' names in Roman type. Price not known.

e-mail: asaccus@aol.com

Mohamad Baloutch of the University of Tehran is the dean of Iranian herpetologists and has introduced the current generation of Iranian students to field biology and natural history. Haji Gholi Kami is one of those former students, now at the University of Gorgan, who is working on amphibians. Their book has been created, apparently, primarily as a guide to amphibiology generally and to the Iranian amphibian fauna specifically for their students.

The first 65 pages cover the biology and taxonomy of amphibians worldwide, drawing information and illustrations from older standard sources, such as Dickerson, 1969, Goin et al. (1978), Porter (1972), Terentjev and Chernov (1949), Thorn (1969), and others. Topics covered include development and metamorphosis, temperature and hibernation, voice, habitat and biocoenosis, life cycles, food, behavior, reproduction, field and museum techniques and brief treatments of taxa, including orders, suborders, and families. Important biological and herpetological terms are followed by the English term in parentheses, presumably as an aid to students reading the Western literature, and one section is devoted to the definition of important terms of external anatomy used in the descriptions and keys.

The remainder of the book deals with the Iranian amphibian fauna and draws upon most of the important primary literature of Iranian and Southwest Asian amphibians as well as upon the experience of the authors. The species accounts include information on natural history, habitat, and distribution, as well as descriptions of the taxa. Keys to all taxonomic levels are included. The bibliography includes 17 titles in Farsi (in Arabic script) and 81 titles in Western languages (in Roman script).

Most of the errors that I noticed are due to typesetters unfamiliar with taxonomic conventions (e.g., capitalization, here and there, of specific and subspecific epithets). The photographs and some other illustrations have not printed well. The authors have followed Eiselt and Schmidtler (1973) and Anderson (1985) in including *Bufo arabicus* Heyden, 1827, as a subspecies of *Bufo viridis*, whereas Balletto et al. (1985) have shown that this name applies to a different toad of the Arabian peninsula (see also Leviton et al. 1992).

Of what interest is a book in Persian designed for Iranian students to readers of *Herpetological Review*, apart from herpetological bibliophiles who feel compelled to collect all such esoterica? For herpetologists interested in Southwest Asia the book provides a complete list of the Iranian amphibian fauna, but more important, the only existing spot distribution maps for each species (although names of localities are not provided). Thus, while I would hardly recommend that all herpetologists seek out this book, it should probably be in the collections of museum departments of herpetology and in the libraries of large research universities.

This monograph on squamate genital structure is the eighth in the *Mertensiella* series, published as a supplement to the more well-known (at least to North Americans) journal *Salamandra*. Previous issues in the series have included primarily edited works on Palearctic amphibians and reptiles and on varanid biology. This treatise expands on earlier work by the authors on the morphology of the hemipenes and the recently described and named hemiclitores of squamate reptiles, especially varanids and their relatives. It also examines the evolutionary and developmental implications of the copulatory organs and their relationship to mating.

The book begins by providing a historical overview of the study of genital morphology and an introduction to cloacal structure and function. The platynotan lizards are introduced with respect to paleontology, distribution, and general characteristics. The materials and methods section is especially valuable as it outlines methods for the preparation of the hemipenes, hemiclitores, and hemibacula. If inappropriately or incompletely everted, many of the structures of potential interest and systematic use may be obscured or uninterpretable. Significantly, it is possible to evert hemipenes of preserved material, allowing researchers to retrieve data from most museum specimens.

As part of their review of copulatory structures Ziegler and Böhme examined *Lanthanotus borneensis*, both living species of *Heloderma*, and 37 of 47 *Varanus* species. The male and female genital organs are described for each species and line drawings or photographs illustrate many of these structures, including the mineralized hemibacula and their female homologues, the hemibaubella. As Böhme has long argued, these structures, especially the hemipenes, are remarkably complex and provide a potential wealth of characters for both functional and phylogenetic analysis. In one of the more controversial interpretations of their study, the authors recognize female choice as the major factor involved with the evolution of such hemipenial complexity.

Hemiclitores are widespread in the Iguania, Gekkota, Amphisbaenia, Serpentes, and Scincomorpha, as well as the Anguimorpha. This will come as a surprise to many herpetologists and has some direct implications for reptile husbandry, as traditional methods of probing may incorrectly identify females with large hemiclitores as males. The female organs appear to represent rudimentary versions of the male genitals that are characterized by smaller size, a lack of a mineralized internal skeleton, and a simplified surface morphology. The authors include some developmental data to support this interpretation and also assess within taxon variability in both hemipenes and hemiclitores (it is minimal).

The authors document a general conservativeness across varanid lizards with respect to genital morphology, but have identified autapomorphies of these organs which they use to erect a new subgenus, *Soterosaurus*, for *Varanus salvator*. Although the value of recognizing such monotypic subgenera may be questioned, they have also identified other genital characters that appear to support the monophyly of previously recognized subgenera of monitors. Perhaps most importantly, features of squamate genitals appear to be useful in alpha systematic studies and may provide evidence of multiple taxa masquerading under a single name.

The monograph is illustrated by 117 figures and 14 pages of color plates. The majority of these illustrations are informative and contribute materially to the text, however some photographs of lizards *in copulo* are probably superfluous and one figure (Plate 1, Fig. E) appears to be missing and has been replaced by a duplicate of the figure intended for Plate 2, Fig. E. The bibliography includes over 400 references, including the majority of papers dealing with the structure, function, and development of the copulatory organs of squamates.

This contribution will be of considerable use to those interested in varanid biology, squamate reproductive morphology, and intersexual homology. However, all squamate systematists will find the techniques of hemipenial eversion valuable and most morphologists will be intrigued by the fact that the complexity of the hemiclitores and associated structures have gone unappreciated for so long. An English summary and bilingual figure captions should make the majority of this valuable work accessible to even non-German readers and the reasonable price (especially for DGHT members) makes this an affordable addition to most herpetological libraries.

Amphibians and Reptiles of the Great Lakes Region, by James H. Harding. 1997. University of Michigan Press, Ann Arbor. xvi +378 pp. Cloth US $42.50 (ISBN 0-472-09628-1) Paper US $19.95 (0-427-06628-5).

JOHN J. MORIARTY
Minnesota Frog Watch, 3800 County Road 24
Maple Plain, Minnesota 55359, USA
e-mail: frogs@tc.umn.edu

Amphibians and Reptiles of the Great Lakes Region is the newest addition to the Great Lakes Environment series from the University of Michigan Press. The series covers a variety of natural history topics dealing with the Great Lakes Basin. Like other books in the series, this book's emphasis is on the recognition and general distribution of all species of amphibians and reptiles in the region. This is a plus for using the book as part of the series, but has some limitations.

The book is organized into three sections: introduction, species accounts, and resources and references. The most unique part of the book is the introduction. In it, Harding details the effects of glaciation on the distribution, evolution, and life history of the amphibians and reptiles found in the region. This is the only book I have seen that explains this important part of ecological and evolutionary history in an easy-to-read manner.

The species accounts make up the majority of the book. The accounts cover all the species of the Great Lakes drainage including peripheral species such as the bog turtle, ravine salamander, slender glass lizard, and short-headed garter snake. The accounts are divided into: Description, Confusing Species, Distribution and Status, Habitat and Ecology, Reproduction and Growth, and Conservation. There is a range map and at least one color photo of each species.

The maps in the book are standardized with the rest of the books in the series; they are centered on the Great Lakes Basin, so most states are only partially covered. Wisconsin and Michigan are the only states that are completely included. The maps are not intended to be exact locality maps, but some of the maps are very imprecise, especially at the periphery. The green snake and Blanding's turtle mapped distributions, for example, are too wide ranging in Minnesota. The photos, however, are uniformly good and clearly show diagnostic features of each species.

The one aspect of the book with which I have the biggest problem is the lack of citations, a fault I have seen in some other recent herp guides. I understand this book is intended to be a general guide, but the back cover does state that this is an essential guide for the professional and private enthusiast. I found myself wanting to know where some of the facts came from. I was also a little concerned with the use of the terms "possibly," "probably," and "may" to describe longevity, size, and other natural history items. Unfortunately, these unsubstantiated "facts" may be cited by others. One example is in the Blanding's turtle account, in which Harding states "... it seems possible that a few individuals may reach the century mark." The oldest known *Emydoidea blandingii* has been reported at 77 years. I can see the day when Harding (1997) will be cited as the source for the longevity record for this species. Caution is in order in such matters.

The conservation section provides information on current threats to the species and some suggestions on how they can be corrected. This will be very useful for wildlife managers and conservation planners.

The last section of the book contains resources and references, including a complete bibliography. I would have liked to see the state herp books from the Great Lakes states in a separate listing or at least highlighted. The inclusion of state wildlife and conservation agency addresses is useful for persons interested in state conservation and regulation issues.

Amphibians and Reptiles of the Great Lakes Region is a good field guide for the region. Many of the states included in the Great Lakes drainage currently do not have an amphibian and reptile guide, and this book will be extremely useful in those areas. The generalist will find that the book will stand alone, while the professional will want, or need, to use it in conjunction with more detailed individual state sources of information. In either case it will be used extensively by herpetologists and conservationists in the Great Lakes Region.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from the Editor (contact information on inside front cover) or from the SSAR web page (http://falcon.cc.ukans.edu/~gpisani/HRinfo.html).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 640		$340
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$190

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

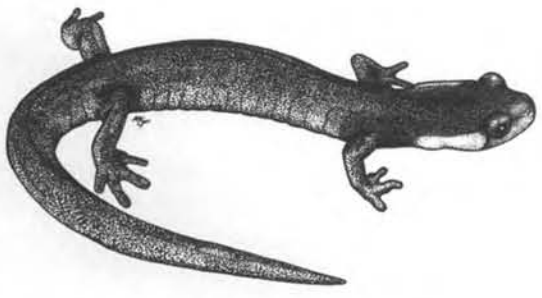
All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1998 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $30; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $24. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

1999 — Pennsylvania State University, University Park, Pennsylvania, USA, 24–30 June (Jay Stauffer, Chair).
2000 — Universidad Autónoma de Baja California Sur, La Paz, BCS, México, 14–20 June 2000 (Carlos Villavicencio, Chair).



About Our Cover: *Plethodon jordani*

Although *Plethodon jordani* is one of the most abundant plethodontid salamanders in the Appalachian Mountains of the eastern U.S., its eggs have never been found in nature. Our cover apparently is the first published photograph depicting its embryos. The eggs were laid spontaneously in the Lynne Houck-Steve Arnold Herpetology Lab at Oregon State University by a female collected on Wayah Bald, Macon County, North Carolina. Of special interest is that although in nature the eggs of *P. jordani* are terrestrial, this clutch was successfully incubated in the lab under flowing water. The incubation technique is described fully by Bernardo and Arnold (Amphibia-Reptilia: in press).

The cover photo was taken by **Bill Leonard**, using a Nikon N90s body, Nikkor 200mm f/4 macro lens, Tamron 2X teleconverter, Nikon 3T close-up lens, a Nikon SB-26 flash, and recorded on Fuji Velvia film. The combination of optics used to make the photo permitted magnifications ranging from 1.5:1 to 3:1. The exposure was made at 1/250th of a second at f/16 with the camera's compensation dial set at +0.7. The camera was mounted on a tripod to maintain steady, sharp focus while the hand-held TTL flash was aimed at the embryos from about a 30° angle above the water's surface. The eggs were placed in a water-filled glass bowl and photographed from above. Jerod Sapp and Robert Storm assisted Bill in setting up the photo in the lab.

Bill Leonard lives in Olympia, Washington, where he works for the Washington Department of Ecology. Bill has lent his writing, editing, and photographic skills to several recent books, including *Amphibians of Washington and Oregon* (1993), *Reptiles of Washington and Oregon* (1995), *How to Photograph Reptiles and Amphibians* (1997), and *Sampling Amphibians in Lentic Habitats: Methods and Approaches for the Pacific Northwest* (1997). He is the managing editor of *Northwest Fauna*, an occasional monograph series published by the Society for Northwestern Vertebrate Biology, and a co-chair of the U.S. Pacific Northwest Working Group of the Declining Amphibian Populations Task Force.

Separation and imaging of Leonard's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

Plethodon jordani. Illustration by Michael G. Frick.

SSAR BUSINESS

1998 Annual Meeting: Guelph, Ontario

The 41st annual meeting of SSAR occurred from 16 to 23 July 1998 in Guelph, Ontario, Canada. Once again this year, SSAR met jointly with The Herpetologists' League and the American Society of Ichthyologists and Herpetologists on the campus of the University of Guelph. The University and the local committee, chaired by Jim Bogart, hosted over 1000 attendees. Most of the meeting's events took place on the campus. The meeting's unofficial opening, the SSAR Board of Directors annual meeting, took place on 16 July between 1430 and 1855 h. In attendance for all or most of the meeting were Elected Officers Darrel Frost, Vic Hutchison, Robert Aldridge, Ellen Censky, R. Wayne Van Devender, John Iverson, and Henry Mushinsky; Appointed officers Kraig Adler, Rich Seigel, Robert Hansen, Brian Crother, and Steve Corn; Committee Chair Dawn Wilson, Ken Dodd, Don Forester, and Julian Lee; Members-at-large Mo Donnelly, David Hardy, and John Moriarty. A summary of business conducted was presented at the Business Meeting (see below).

Presentations

The meeting officially opened at 0815 h on 17 July at War Memorial Hall with opening remarks and announcements by Jim Bogart followed by a welcome from the University's president. That was followed by Harry Greene's presentation of the ASIH Henry S. Fitch Award to A. Stanley Rand in recognition of his major contribution to herpetology. The HL Distinguished Herpetologist this year was Sharon Emerson who presented a talk entitled "The evolution of morphological novelties." And then there was a shark talk.

A total of 545 talks and 112 posters were presented in 65 oral presentation sessions and four poster sessions. There were eight symposia at the meetings this year, however, none of them was sponsored by SSAR. SSAR did host the Conservation Forum on 20 July and the topic this year was "CITES: Benefit or hinderance to the conservation of amphibians and reptiles." This Forum was organized by Ken Dodd and the Point-Counterpoint speakers were Michael Klemens, Brian Bowen, and Sue Lieberman.

Social Programs

In addition to the scholarly activities at the meetings, there was a wealth of social activities and special events in which to partake. The social activities were kicked off with the General Reception, held at the University Centre on 16 July. Fine edibles and liquid refreshments were served. Herpetologists and ichthyologists alike were entertained the next evening (17 July) by Bob Murphy, Leslie Lowcock, and Ross MacCulloch's encore performance of ROMMY, ROMMY II. The evening started with the stand-up comedy of David Green and continued with "The World's First Phylogenetic Rock Opera" performed by the aforementioned and their talented crew of graduate students, post docs, etc.

The Ontario Herpetological Society and the Department of Zoology, University of Guelph sponsored the exhibit "Living Amphibians and Reptiles of Ontario." Living representatives of most species from Ontario were on display throughout most of the meetings, providing a great opportunity for photography buffs.

The picnic was held on 20 July at Guelph Lake Conservation

area. As soon as the first steaks hit the grill, the beer began to flow. Dancing ensued soon after the food was eaten and continued until the last bus arrived to retrieve its passengers. On the last evening, 22 July, the more reserved Banquet was held at the University Centre.

Among the several hundred picnic attendees, Kraig Adler, Betty Taylor, and Doug Taylor listen to another of Jim Murphy's implausible, but true, tales of zoo life.

Two of the traditional SSAR activities, the auction and the multimedia show, had their problems. Dave Dennis and Eric Juterbock were on their way to the meetings with multimedia show in tow and ended up with van in tow. They were unable to complete the journey. Hence, the show did not go on. The auction came off without a glitch, but that was due to the quick action and quick wittedness of Darrel Frost. Joe Collins found himself in the hospital just a few days prior to the meeting and had to cancel as auctioneer. Darrel took up the call and according to many has missed his calling. Meeting host Jim Bogart—AKA "Beer Fairy"— dispensed tickets for beers and the auction, held at the Brass Taps on 21 July, was a great success, with over $3500 being raised. The Silent Auction was also successful with over 50 works of art donated. As usual, it ended with a bang with lots of bids coming in at the last minute. The amount raised by the Silent Auction for Student Travel Awards next year was $1400.

Business Meeting

President Darrel Frost called to order the 41st Annual Business Meeting of the SSAR at 1030 h in Axelrod Room 200 on the campus of the University of Guelph on Tuesday, 21 July. He reported on the upcoming meetings in 1999 at Penn State—another three-way meeting (with HL and ASIH)—and remarked on the unremarkable effort that we have made in trying to secure future meeting sites. He appointed Henry Mushinsky as chair of a committee to seek sites for future herpetology meetings. Frost also reported on the Joint Directory, stating that names of members from all three societies have been integrated and duplicates purged. He hoped that the directory would be completed by September, but noted that all three societies had not yet signed a Memorandum of Agreement towards its use and distribution. This would be done soon.

There were several people who were recognized for their services to the society. In addition, new appointments were announced. Ken Dodd was thanked for his untiring effort towards matters dealing with conservation. Dodd resigned as Chair of the Conservation Committee and Michael Klemens was appointed to that position. Julian Lee resigned from the Grants-in-Herpetology committee after four years as Chair and two years as a member of the committee. The society recognized his contributions over the years. Joseph Mendleson was appointed to Chair GIH. Julian was also thanked for his efforts as Associate Editor of *Journal of Herpetology*. Geoffrey Smith has been appointed to replace him. Dave Hardy was acknowledged for his job as elector, and was replaced by Christopher Raxworthy. Robin Andrews was thanked for chairing the Nominations Committee and Henry Mushinsky was appointed as the new chair. The membership expressed its gratitude to John Lynch for having served as CAAR section editor for Anura and as Associate Editor of JH. Hinrich Kaiser was appointed to the CAAR position and Eric Wild to JH. Lee Fitzgerald resigned and Hal Avery and Sharyn Marks were appointed as Associate Editors for *Herpetological Review*.

Treasurer Robert Aldridge reported that our membership remained steady at 2571 but that our expenditures had exceeded our income. This prompted the board to raise the dues by $10 for all members except students, to $95 for Institutional subscriptions, and to $25 for "HR only" category. He reported that the board had approved a 1999 budget of $208,310.

Secretary Censky reported much of the remaining business conducted at the Board Meeting. In addition to the aforementioned resignations and appointments to the *Journal of Herpetology*, Dirk Bauwens and Peter Ducey were added to the Editorial Board. The board authorized the placement of JH abstracts on the Allen Press web site with a link to the SSAR homepage. The cost of page charges for JH were lower in 1998 than in 1997, and Editor Seigel will continue to seek ways to reduce the costs of the journal. *Herpetological Review* editor Robert Hansen noted that during his tenure the number of pages per issue had doubled from 32 in 1991 to 64 today. He reported that the journal is doing well and he is also seeking ways to reduce costs.

Beer frenzy. Government regulations prevented the serving of beer at the Guelph Lake picnic when the crowd arrived and for some time afterwards. However, at the officially sanctioned moment, herpetologists and ichthyologists surged forward to quench their thirst.

The *Catalogue of American Amphibians and Reptiles* report to the board stated that there had been a delay in production of the 1997 accounts associated with shifting to a total in-house pro-

Godfather and Zen Master: Carl Gans and Richard Etheridge at the banquet.

duction. Because of the in-house production, expenditures were down. CAAR is back on track. Facsimiles editor Kraig Adler reported that two works will be published in 1998: "Contributions to the Herpetology of the Belgian Congo," by Karl P. Schmidt and G. K. Noble and "The Gigantic Land Tortoises of the Galapagos Archipelago," by John Van Denburgh. There was also one Contribution published in 1998: "Biology of the Reptilia, volume 19: Visceral Organs," edited by Carl Gans and Abbot Gaunt. Future publications include "Lizards of Iran," by S. C. Anderson; "Anatomy of the Salamander," by E.T.B. Francis; "Herpetofauna of New Caledonia and Surrounding Islands," by A. Bauer and R. Sadlier; "General Zoology: volume 3 Amphibia," by G. Shaw; "Amphibians of Honduras," by J. R. McCranie and L. D. Wilson; and "Herpetological Illustrations from the Spencer Library, University of Kansas," compiled by S. Haines. It was reported that *Herpetological Circulars* will publish "Venomous snakes: A Safety Guide for Keepers," by W. Altimari, and "Lineages of Zoo Herpetologists in the United States," by W. Card and J. B. Murphy. *Herpetological Conservation* has accepted a proposal from Michael Lambert for an edited volume of papers on ecotoxicology of amphibians and reptiles.

Always in search of new resolutions, Julian Lee brings his briefcase to the picnic, as Greg Pregill and Ellen Censky admire Julian's dedication to the Society.

Chair Brian Crother described the new structure of the Standard English and Scientific Names Committee. He stated that he had created sub-committees to handle each of the major taxonomic groups and that a manuscript should be ready this fall. In addition to standardized common names, this publication will include scientific names in debate and describe the nature of the debate. He stated that they will also publish a paper describing the goals of the committee.

Ken Dodd, Chair of the Conservation Committee, reported that the committee had produced a brochure on conserving amphibians and reptiles, and he thanked George Pisani for putting it on the Web. Hard copies are available from Mike Klemens or Dodd.

Julian Lee, Chair of the Grants-in-Herpetology Committee, reported that the program was thriving. There were 53 proposals received. The committee was composed of Julian, Anne Maglia, Joseph Mendelson, Janice Perry, and Kelly Zamudio.

Julian Lee also read proposed resolutions, which were then accepted by the membership. Resolutions are presented below.

The Kennedy Award Committee (Ken Marion, chair, Robin Andrews, Dave Duvall, Robert Gatten, and Terry Schwaner) reported that there were 15 manuscripts in competition this year and the winner was "The effects of reproductive mode and climate on reproductive success in the Australian Lizard, *Lerista bougainvillii*" by Carl Qualls.

The Student Travel Award Committee (Todd Esque, Roy Mark Waters, and Dustin Haines) presented 10 awards of $200 each. In addition, they secured several items for the silent auction at Guelph. Dawn Wilson has been appointed to oversee this committee. John Wiens, Chair of the Seibert Award Committee, reported that there were 34 presentations entered into competition. The judges included Brad Shaffer, Dawn Wilson, Steve Tilley, Steve Poe, Kelly Zamudio, and John Wiens. Chuck Crumly of Academic Press donated a book to the winner in each category and all honorable mentions.

Mike Tyler, representing the Executive Board of the World Congress of Herpetology, reported that the next World Congress will be in Sri Lanka, probably in the year 2001.

Nominations for election to SSAR office for 1999 were presented and accepted by the membership. President-elect: David Green and Julian Lee; Secretary: Ellen Censky; Treasurer: Robert Aldridge; Director (Class of 2001): Maureen Donnelly and Lee Fitzgerald; Director (non-US): Akira Mori and Richard Wassersug.

—Respectfully submitted by Ellen J. Censky, Secretary.

1998 Resolutions

Honoring David Wake

WHEREAS, David B. Wake has made many important contributions to our knowledge of evolutionary morphology, and of the systematics and ecology of salamanders; and

WHEREAS, David B. Wake has done much to elucidate the nature of global amphibian population decline, and to raise public awareness of this important issue; and

WHEREAS, David B. Wake was recently elected to membership in the National Academy of Sciences,

THEREFORE, be it
RESOLVED that the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for

the Study of Amphibians and Reptiles offer congratulations to David on the occasion of this high honor, richly deserved.

Declining Amphibians

WHEREAS, there is compelling evidence that, over the last 15 years, there have been unusual and substantial declines in abundance and numbers of populations of various species of amphibians in globally distributed geographic regions; and

WHEREAS, many of the declines are in protected areas or other places not affected by obvious degradation of habitats; and

WHEREAS, these factors are symptomatic of a general decline in environmental quality; and

WHEREAS, even where amphibian populations persist, there are factors that may place them at risk; and

WHEREAS, some patterns of amphibian population decline appear to be linked by causative factors; and

WHEREAS, declines can occur on multiple scales, in different phases of amphibian life cycles, and can impact species with differing ecology and behavior; and

WHEREAS, there is no obvious single common cause of these declines; and

WHEREAS, amphibian declines, including species extinctions, can be caused by multiple environmental factors, including habitat loss and alteration, global climate change, pathogens, parasites, various chemicals, ultraviolet radiation, invasive species, and stochastic events; and

WHEREAS, these factors may act alone, sequentially, or synergistically to impact amphibian populations; and

WHEREAS, to understand, mitigate, and preempt the impacts of these factors, a comprehensive, interdisciplinary research program must be undertaken; and

WHEREAS, this research program must be conducted in several regions around the globe, both in areas of known declines, and in areas where declines have not been documented; and

WHEREAS, this research must examine issues ranging from environmental quality of landscapes to the condition of individual animals,

THEREFORE, be it
RESOLVED, The American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and The Society for the Study of Amphibians and Reptiles call for the establishment of an interdisciplinary and collaborative research program, which will specify and quantify the direct and indirect factors affecting amphibian population dynamics; and be it

FURTHER RESOLVED that this program will include basic research and monitoring that will test hypotheses of causative factors and examine patterns of change through historical records, field-based correlative data, and controlled, multi-factorial experiments; and be it

FURTHER RESOLVED that interdisciplinary, incident response teams should be assembled in "hot spots" of amphibian decline to identify causative factors to facilitate the mitigation of these sudden declines; and be it

FURTHER RESOLVED that The American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and The Society for the Study of Amphibians and Reptiles call upon both public and private agencies and institutions to promote and support research, policies, and conservation measures that will ameliorate losses and declines of amphibian populations; and be it

FURTHER RESOLVED that this broad-based approach to the study of amphibian population dynamics will serve as a model for study of the global biodiversity crisis.

Commercial Collecting

WHEREAS, there is an unrelenting demand for the commercial collection of amphibians and reptiles, and

WHEREAS, natural populations of amphibians and reptiles must maintain a minimum critical density in order to prevent population collapse, and

WHEREAS, information on the persistence of natural populations of amphibians and reptiles is often unavailable, and

WHEREAS, natural populations of amphibians and reptiles have collapsed under the pressure of commercial collecting, and

WHEREAS, there exist state and national laws regulating scientific collecting, in order to prevent illegal activities and to protect wildlife, but commercial collecting in some states is virtually unregulated,

THEREFORE be it
RESOLVED that The American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and The Society for the Study of Amphibians and Reptiles encourage all appropriate wildlife agencies to work with ASIH, HL, SSAR and other scientific organizations to take appropriate measures to regulate commercial collecting in states where such collecting is allowed.

Thanks to Local Committee

WHEREAS, the 1,040 attendees at the meeting of the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles at The University of Guelph have enjoyed a stimulating, informative, and entertaining program of contributed papers, posters, symposia, and social events, and

WHEREAS, hosting such meetings involves an enormous expenditure of time, energy, and resources on the part of Local Committee members, and

WHEREAS, said Local Committee members have given selflessly of themselves in the service of our societies, and have done so with grace, good humor, and generosity of spirit, to the benefit of all attendees,

THEREFORE be it
RESOLVED, that we, the assembled members of the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles acknowledge our deep debt of gratitude to the University of Guelph, its administrators, and the following members of the Local Committee, and we extend to them our sincere thanks for their efforts on our behalf. Bob Sheath, Dean, College of Biological Sciences; Paul Hebert, Chair, Department of Zoology; Local Committee Members Jim Ballantine, Bill Beamish, Ronald J. Brooks, Steve Crawford, Roy Danzman, Sonia deRincion, Joshua Feltham, Moira Ferguson, Cyndy Forsyth, David Galbraith, Megan Harris, Tim Jennings, Lori Kirsh, Amy Lathrop, Angie Lightle, Heather Lynn, Steve Marks, Ian Mason, Tom Mason, Tana McDaniel, Clair Morris, Bob Murphy, David Noakes, Mike Rankin, Marie Rush, Leslie Rye, Ian Smith, Ildiko Somorjai, Don

Prepublication Announcement

VENOMOUS SNAKES: A SAFETY GUIDE FOR REPTILE KEEPERS

WILLIAM ALTIMARI

A New Herpetological Circular from the Society for the Study of Amphibians and Reptiles

HERPETOLOGICAL CIRCULAR NO. 26

This long-awaited publication contains a wealth of information about the habits, sizes, venom yields, symptoms of envenomation, and temperaments of 59 species of snakes of the families Elapidae and Viperidae. All of the species of snakes featured herein are currently represented in the herpetological collections of North American zoos, and this booklet makes vital information about them quickly available. Includes an Introduction as well as sections on Equipment and General Guidelines, followed by the Species Accounts, and ending with sections on Venoms and Conclusions. Contents and Literature Cited. iv + 24 pages. ISBN 0-916984-47-8. September 1998.

This SSAR publication partially financed and co-sponsored by
THE CENTER FOR NORTH AMERICAN AMPHIBIANS & REPTILES

Prices:	
Prepublication price *(SSAR members only)*	US $4.00
After 15 January 1999	US $6.00
Shipping:	
First copy	US $2.00
Subsequent copies	US $1.00

Send orders to: Dr. Robert D. Aldridge, Department of Biology, Saint Louis University, 3507 Laclede Ave., St. Louis, Missouri 63103-2010, USA. *Telephone* 314/977-3910; *fax* 314/977-3658; *e-mail*: ssar@sluvca.slu.edu. Make checks payable to "SSAR." Overseas orders must be paid in USA funds using a draft drawn on American banks or by International Money Order. Orders may be charged to VISA or MASTERCARD (account number and expiration date must be provided). SSAR membership details and a complete list of Society publications can be obtained on request to Dr. Aldridge.

Stevens, Glenn Vander Kraak, and especially Jim Bogart, Chair of the Local Committee.

Non-Substantive Resolutions

WHEREAS, more ichthyologists and herpetologists are beginning to enter the 20th Century and are using computer technology more and more to produce slide extravaganzas, and

WHEREAS, certain herpetologists from the Royal Ontario Museum have resurrected ROMMY and raised it to new musical and theatrical heights, and

WHEREAS, with these influences it is expected that ASIH/HL/SSAR presentations will use music, theater, and computer technology more and more frequently to entertain while educating,

THEREFORE be it
RESOLVED that new Stoye award categories be devised to reflect:
Best special effects
Best sound track
Best vocal...

WHEREAS, it first seemed that the solution to having too little beer for the picnic was to refuse to serve those in attendance, and

WHEREAS, the arcane regulations imposed by various and sundry government agencies on beer drinking at the picnic has forever changed the meaning of "Excuse me, sir, may I hold that for you?" for one member whose need was more pressing than the line to the portolets allowed, and

WHEREAS, the Local Committee resolved any potential shortages by calling the Molson Rapid Response Team van at 1-800 MOLSON eh?

THEREFORE be it
RESOLVED that those in attendance at the picnic express their sincere appreciation to the Local Committee for working so hard to resolve the many obstacles imposed by the government on Canada's National Pastime, and be it

FURTHER RESOLVED that each U.S. delegate be sent home with a six pack of Coors Light so that the Local Committee needn't suffer the indignity of having so much undrinkable swill on their hands.

WHEREAS, the Guelph Local Committee has graciously commissioned the Canadian Treasury Department to print and distribute a special $10.00 banknote honoring American Herpetologist Dr. Craig Guyer,

THEREFORE be it
RESOLVED that at all future meetings of the ASIH, HL, and SSAR, similar commemorative legal tender be commissioned in honor of other prominent ichthyologists and herpetologists.

WHEREAS, even the thought of a dry campus strikes terror into the hearts of attendees of these meetings, and

WHEREAS, said delegates were greatly relieved to learn that the "wet" and"dry" containers around campus were not part of a campaign to alter their drinking habits but were instead a laudable recycling program, and

WHEREAS, many other aspects of these meetings have been conducted in an environmentally friendly manner, including but not limited to Ecorite cottontote bags, scrumptious vegetarian options at mealtime, beverage dispensers rather than canned or bottled drinks during breaks (including quality draught rather than bottled beer) and of course minimal use of airconditioning,

THEREFORE be it
RESOLVED that the attendees at these meetings commend the University of Guelph and the Local Committee for their efforts at conserving energy and natural resources.

WHEREAS, Richard Etheridge has been an early, if not founding, member of all three North American herpetological societies, and

WHEREAS, Richard Etheridge has faithfully served these three societies in various capacities for over four decades, this being the 50th meeting that he has attended, and

WHEREAS, despite his soft-spoken, humble, zen countenance, Richard Etheridge has been one of the most influential herpetologists of the past century, and

WHEREAS, Richard's dedication to herpetology has been nothing less than extraordinary and has included great personal sacrifices, including dating daughters of certain deceased herpetologists in order to acquire full reprint sets of said herpetologists' work, and

WHEREAS, Richard credits William Milstead with teaching him that "herpetology is more than keeping snakes in cages," and

WHEREAS, despite this advice, Richard has spent his adult life rendering various reptiles into skeletons which he keeps in cardboard boxes, and

WHEREAS, Richard Etheridge is the only herpetologist to be envenomated by a dead speckled rattlesnake, and

WHEREAS, Richard's research efforts have resulted in the frustration of curators world wide who were compelled to change jar labels for millions of specimens once considered to belong to the family "Iguanidae," and

WHEREAS, Richard worked at a university where only Masters degrees were awarded, and

WHEREAS, despite this limitation, Richard's students produced theses which often exceeded 500 pages, bound as two volumes, and

WHEREAS, said students are some of today's most widely respected and influential herpetologists, and

WHEREAS, Richard Etheridge recently retired from San Diego State University,

THEREFORE be it
RESOLVED that at next year's meeting at Penn State University, the three societies, its members, and especially his students and colleagues honor Dr. Richard Etheridge with a day-long symposium and nighttime "roast," and be it

FURTHER RESOLVED that from this day forward Richard be referred to as "The Godfather and Zen Master of Lizard Systematics."

WHEREAS, we ran out of beer at the social, and

WHEREAS, no beer was available at the barbecue, and

WHEREAS, the term microbrew does NOT refer to QUANTITY,

THEREFORE be it

RESOLVED that future Local Committees review the data gathered by the Local Committees in Austin, New Orleans, and Seattle showing that volume increases exponentially with surface area of the members.

Seibert Award Winners for 1998 Announced

The seventh annual Seibert Awards were presented at the 41st Annual Meeting of the SSAR in Guelph, 16–23 July 1998. These awards are named in honor of Henri C. Seibert, an early and tireless supporter of SSAR (having served as an officer for over 20 years). In recognition of outstanding student presentations at the annual meetings, a single award was given in each of the following categories: Systematics (3 eligible presentations), Ecology/Evolution (17), Physiology/Morphology (4), and Conservation (7). All four awardees received a check for US $200 and a book from Academic Press.

The Winners.—Conservation: Martin Schlaepfer, Department of Natural Resources, Cornell University, "The effects of forest-pasture edges on the herpetofauna of Fila Cruces, Costa Rica." Ecology/Evolution: Richard Glor, Section of Ecology and Systematics, Cornell University, "Reptile diversity in a disturbed tropical forest landscape." Systematics: Anne Maglia, Natural History Museum and Department of Systematics and Ecology, University of Kansas, "Comparative osteology and phylogenetic relationships of the pelobatid frogs (Anura: Pelobatidae)." Physiology/Anatomy: Jason Irwin, Department of Zoology, Miami University, "Freeze avoidance and terrestrial overwintering in the northern cricket frog, *Acris crepitans*."

Honorable Mention.— Conservation: M. B. Kolozsvary, Department of Forestry and Natural Resources, Purdue University, "Amphibian species distribution patterns in an agriculturally-fragmented landscape." Ecology/Evolution: Sharon Downes, School of Biological Sciences, University of Sydney, "Do incubation-induced changes to a lizard's phenotype affect its vulnerability to predators?" Physiology/Anatomy: Philip Martin, Department of Biological Sciences, Ohio University, "Adaptation to life in estuarine environments in the northern water snake (*Nerodia sipedon*)."

The judges were: John Wiens, chair (Carnegie Museum of Natural History), Steven Poe (University of Texas, Austin), Brad Shaffer (University of California, Davis), Steve Tilley (Smith College), Dawn Wilson (University of Nevada, Reno), and Kelly Zamudio (University of California, Berkeley).

ASIH-HL-SSAR 1999 Meeting Update

Meetings organizers of the 1999 ASIH-HL-SSAR meetings at Penn State have changed deadlines related to abstract submission and modification as follows:

Abstract submission deadline for acceptance: 1 February 1999. Final abstract text may be changed until: 15 March 1999.

SSAR Student Travel Awards Call for Applications

Awards of US $200 each are available. An applicant for a travel award must be a student and a member of SSAR, must not have previously received a travel award from SSAR, and must be the first author (or co-author, see below) of a paper or poster to be

presented. An applicant must include in the application package: 1) a letter signed by his/her major advisor or department chair that states: he/she is not completely funded for travel from another source; 2) an official copy of the poster or paper abstract to be presented; 3) a self-addressed, stamped envelope.

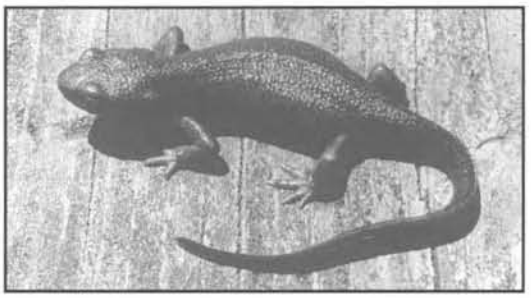
If the research is co-authored, the applicant must also include a letter from his/her advisor stating that the work was primarily the product of the applicant. All qualified applicants will be pooled and awardees will be drawn at random. Students from the local meeting site and current members of the SSAR Student Travel Awards Committee are excluded from applying for a travel award.

APPLICATIONS MUST BE POSTMARKED BY 15 MAY 1999. Award recipients will be notified by 1 June 1999 and award checks will be disbursed at the meeting. Direct requests for information to: *Lance D. McBrayer, Department of Biological Sciences, Ohio University, Athens, Ohio 45701, USA: Tel. (740) 593-2351; e-mail: lance.mcbrayer@ohio.edu.*

SSAR Student Awards Fund-raiser: 1998 Results and Call For 1999 Donations

Thanks to the many generous donations from several individuals to the 1998 silent auction in Guelph, the SSAR Student Travel Awards Committee (SSAR STAC) awarded ten US $200 travel grants to the following individuals: Christine Bridges, Sharon Downes, Kevin Jansen, Mark Jordan, Jason Kolbe, Matt Lovern, Philip Martin, Matthew Parris, Carol Spencer, and Nicole Valenzuela. The SSAR STAC wishes to thank all who donated items to the 1998 auction in Guelph. The fourth annual Frameable Art Silent Auction raised over $1300 for future student travel awards. On behalf of SSAR and the SSAR STAC Chairman, Todd Esque, thanks to all who helped, including Dustin Haines, Roy Mark Waters, Tana McDaniel, and the Guelph meeting organizers.

The SSAR STAC announces the Fifth Annual Frameable Art Silent Auction to be held at the 1999 SSAR meeting at Penn State. Preferred donations include herp-related photos, line drawings, prints, paintings, plates, engravings, or anything frameable, if not already framed. If you are interested in donating an item (tax deductible for U.S. residents), please contact: *Lance D. McBrayer, Department of Biological Sciences, Ohio University, Athens, Ohio 45701, USA: Tel. (740) 593-2351; e-mail: lance.mcbrayer@ohio.edu.*



Grants-in-Herpetology Donations Sought

Financial contributions by SSAR members, institutions, and other benefactors support this program significantly and can increase the number and/or size of awards. Your tax-deductible (for U.S. residents) contribution to this program will directly benefit meritorious research and education in herpetology. Contact the Treasurer of SSAR for additional information on contributing to the Grants-in-Herpetology Program. If you are employed by an organization that will match donations made to nonprofit organizations, please notify your employer that you have made a donation to the Grants-in-Herpetology Program.

Biology and Conservation of Sea Turtles
Revised Edition
EDITED BY KAREN A. BJORNDAL
"If one were limited to a single reference text on sea turtle biology and conservation, this would be the one to acquire."—*Reptiles*
8 b&w illus., 99 tables, 98 figures, 22 maps • 584 pp.
Paperback $29.95

NEW IN PAPERBACK
The Reptiles of Virginia
JOSEPH C. MITCHELL
FOREWORD BY ROGER CONANT
"This book is recommended to anyone interested in the herpetology of the middle Atlantic Region, and Virginia in particular."
—*Herpetological Review*
"There is much to recommend about this book. The production standards are first-rate, the layout is attractive, the photographs are excellent, the range of maps are comprehensive and the voluminous literature on Virginia reptiles has been completely surveyed and incorporated."—*Reptiles*
63 color, 9 b&w illus., 65 maps • 368 pp.
Paperback $24.95

Salamanders of the United States and Canada
JAMES PETRANKA
This comprehensive volume, the first survey of North American salamanders published since 1943, describes the ecology, evolution, biodiversity, behavior, and natural history of 127 recognized species, from newts and sirens to waterdogs and hellbenders. In detailed life history accounts and nearly five hundred photographs, the book presents a wealth of information on such topics as identification, systematics, courtship and breeding, diet and predation, and the ecology of larval and adult stages.
172 color, 311 b&w photographs, 9 line drawings, 128 maps • 592 pp. • Hardcover $60.00

Rattlesnake
Portrait of a Predator
MANNY RUBIO
FOREWORD BY WILLIAM S. BROWN
Illustrated with dramatic original color photographs depicting not only fangs and rattles but also intricate patterns and extraordinary camouflage, *Rattlesnake* traces the evolution and behavior of more than eighty living species and subspecies of rattlesnakes—from East Coast timber rattlesnakes to California's desert-dwelling sidewinders to South America's neotropical species.
263 color photographs • 272 pp. • Hardcover $39.95

AVAILABLE IN BOOKSTORES OR FROM
Smithsonian Institution Press PO BOX 960 • HERNDON, VA 20172 • 800/782-4612 • (FAX) 703/661-1501

NEWSNOTES

Herplit Database

The Herplit Database, maintained by Breck Bartholomew, consists of approximately 30,000 herpetological citations. These citations may be searched and specific citations selected and e-mailed to you (the citation, not the publication). This can be especially useful for persons doing literature searches. To access the site, go to: http://www.herplit.com/herplit.

Changes at Louisiana State University

Effective 19 December 1998, Douglas A. Rossman retired from his position as Curator of Amphibians and Reptiles in the Museum of Natural Science at Louisiana State University, a position he held for 35 1/2 years. He intends to continue his research in snake systematics and welcomes continued correspondence and reprint exchanges with colleagues working in this area.

Rossman's successor at LSU will be Jimmy A. McGuire, who assumes the post on 1 January 2000. During 1999, all loan requests and other correspondence pertaining to the collection of Amphibians and Reptiles should be directed to Frank T. Burbrink at the Museum of Natural Science, 119 Foster Hall, Louisiana State University, Baton Rouge, Louisiana 70803, USA. Tel. 225-388-3082, e-mail: fburbri@unix1.sncc.lsu.edu, Fax: 225-388-3075.

Adler Assumes New Role at Cornell

Kraig Adler, one of SSAR's founders and long-time professor of biology at Cornell University, has been named Vice Provost for Life Sciences, a position within the research administration. Adler will serve in his new role on a half-time basis and will continue his research and teaching activities within the Section of Neurobiology and Behavior. His new duties involve coordination of research activities in the life sciences and will help focus the university's attention on new areas of opportunity, such as genomics and biodiversity.

Southwestern Research Station Positions And Grants For 1999

VOLUNTEERS—Approximately 30 volunteer positions are open in 1999 at the American Museum of Natural History's Southwestern Research Station in Portal, Arizona. The volunteer program is run annually and offers students in biological sciences outstanding opportunities to observe and become involved with scientists doing field research. Food and lodging are provided to volunteers in exchange for twenty-four hours per week of routine chores, with the remaining time available for research activities.

The program is open to both undergraduate and graduate students; the latter may pursue their own research projects. Faculty knowing of promising students should alert them to this opportunity for professional experience toward, development of, and evaluation of their career goals.

Volunteers are needed between March 14 and November 1. Appointments are for part of this period, with a minimum appointment of six weeks. Applicants for spring positions (March–May) should submit applications by February 15, summer volunteers (June–August) by April 1, and fall volunteers (September–November) may apply any time.

For applications, write: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SOUTHWESTERN RESEARCH STATION STUDENT SUPPORT FUND—The American Museum of Natural History awards several grants each year of approximately $400–$800 to graduate students or postdoctoral students pursuing research at its Southwestern Research Station in the Chiricahua Mountains, Portal, Arizona.

Information and application forms for this program and other Museum grant programs can be obtained by writing: Office of Grants and Fellowships, American Museum of Natural History, Central Park West at 79th Street, New York, NY 10024-5192, USA. Application due date: February 15, 1999. Address questions concerning the Station to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, Portal, Arizona 85632 USA; tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

SEASONAL OFFICE ASSISTANT—Assist in operations of biological research station office and nature shop: taking reservations, answering phones, greeting guests, supervising volunteers, etc. Begin March 14, 1999, through September 1999. Five-day week; salary $235/wk, plus room (shared) and board. Applicant must be punctual, organized, enjoy people, and be interested in living in a remote setting (Chiricahua Mountains) and working with biological researchers. Biological training an asset. Call and send résumé to: *Dr. Wade C. Sherbrooke, Director, Southwestern Research Station, American Museum of Natural History, Portal, Arizona 85632, USA. tel. and fax: 520-558-2396; e-mail: swrs@amnh.org.*

MEETINGS

Meetings Calendar

2–6 March 1999—19th International Symposium on Sea Turtle Biology and Conservation, South Padre Island, Texas, USA. Contact Jane Provancha, Symposium Secretary, Aquatics Ecological Program, DYN-2, Kennedy Space Center, Florida 32899, USA; e-mail: Jane.Provancha-1@ksc.nasa.gov; Fax: (407) 853-2939.

15–16 March 1999—Conference: "Population Viability Analysis: Assessing Models for Recovering Endangered Species," San Diego, California, USA. *Further details below.*

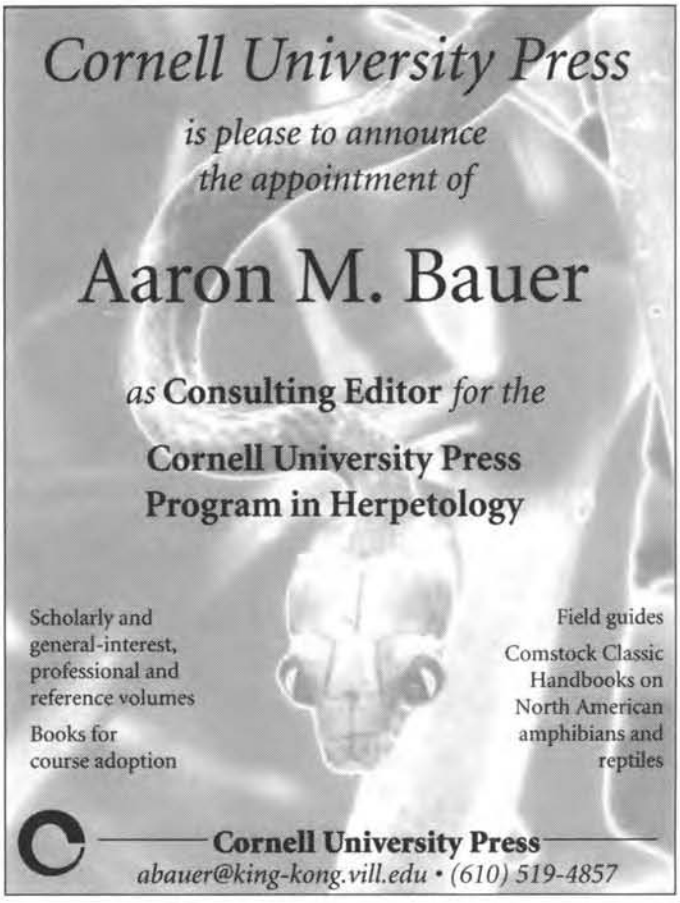
13–17 May 1999—Fourth International Symposium on Isolated Vertebrate Communities in the Tropics, Bonn, Germany. Hosted by the Zoologisches Forschungsinstitut und Museum Alexander Koenig. To receive announcements and to obtain further information, please contact: Prof. Dr. W. Böhme, Adenauerallee 160, 53113 Bonn, Germany; tel. +49 228 91 22 250, fax ++49 228 216 979, e-mail: r.hutterer.zfmk@uni-bonn.de.

5–9 October 1999—The Sixth Annual Conference of the Association of Reptilian and Amphibian Veterninarians, Columbus, Ohio, USA. For Conference registration information contact: Wilbur Amand, VMD, PO Box 605, Chester Heights, Pennsylvania 19017, USA; fax: 610-892-4813.

8–11 October 1999—Second Symposium on the Status and Conservation of Florida Turtles, Eckerd College, St. Petersburg, Florida, USA. Contact: Gopher Tortoise Council, c/o George L. Heinrich, 1223 Alhambra Way S., St. Petersburg, Florida 33705-4620, USA; tel. (813) 865-6255; e-mail: highpine@gte.net.

12–17 December 1999—5th Latin American Congress of Herpetology, University of Uruguay, Montivideo, Uruguay. *Further details below.*

22nd Annual All Florida Herpetology Conference and First Annual Herpetology Education Institute



The 22nd Annual All Florida Herpetology Conference will be held 14–16 May 1999, in Gainesville, Florida, USA. This popular event traditionally has drawn over 400 participants and has now been expanded to three days and will be held at the Radisson Hotel to make room for the more than 600 amateur and professional herpetologists, breeders, veterinarians, and educators that are expected to participate. In addition to addressing issues of global importance such as disappearing amphibians, habitat conservation, and enforcement of protected species regulations, the All Florida Herp Conference will offer informative exhibits with live reptiles and amphibians, herp identification contests, multimedia presentations, and informational sessions. The Herpetology Education Institute on Friday and Sunday will feature hands-on workshops and field trips for all ages. The Conference and Institute are Co-sponsored by the Florida Museum of Natural History and the Gainesville Herp Society. Supporters this year are Ashton, Ashton & Associates, Inc. and the Jacksonville Zoo. For additional information, please contact either of the meeting co-chairs: Ray E. Ashton, Jr., Executive Director, Ashton, Ashton & Associates, Inc., 5745 SW 75th St. #331, Gainesville, Florida 32608, USA, tel. (352) 495-7433 or 495-7449, e-mail: Tortfarm2@aol.com; or Max Nickerson, Curator, Florida Museum of Natural History, P.O. Box 117800, Gainesville, Florida 32611, USA, tel. (352) 392-1721, e-mail: maxn@flmnh.ufl.edu.

5th Latin American Congress of Herpetology

The 5th Latin American Congress of Herpetology (5th CLAH) will be held at the University of Uruguay, Montevideo, Uruguay, 12–17 December 1999. The official languages of the 5th CLAH will be Portuguese and Spanish. However, English and other languages will be accepted in workshops, symposia, and poster presentations but will need to be accompanied by an abstract in one of the official languages. Deadline for Abstracts is 30 June 1999. For registration and additional information please contact Lic. José A. Langone, Secretario Ejecutivo V CLAH, Museo Nacional de Historia Natural, CC 399, 11000 Montevideo, Uruguay, e-mail: vclah@fcien.edu.uy. Additional information and updates will be posted at: http://zvert.fcien.edu.uy/clh. For further information and registration within the U.S. and Canada, please contact: Dr. Rafael de Sá, Department of Biology, University of Richmond, Richmond, Virgina, 23173, USA; e-mail: rdesa@richmond.edu.

Population Viability Conference

A conference entitled "Population Viability Analysis: Assessing Models for Recovering Endangered Species," sponsored by the University of California Berkeley and the Western Section of the Wildlife Society, will be held 15–16 March 1999 in San Diego, California, USA, at the Town and Country Hotel in Mission Valley. Population Viability Analysis (PVA) has become an important tool for assessing risks to endangered species, but has been criticized for the unrealistic ways that models have been applied in management and policy decisions. This conference will focus on issues in the development and application of demographic and genetic PVA models for conserving threatened and endangered species. Themes of conference sessions include conceptual issues in the development of PVA models, integrating theory and practice in the use of PVA, applications of PVA to conservation problems, and the future of PVA. The meeting will consist of presentations by invited speakers including M. Soulé, R. Lande, M. Gilpin, M. Boyce, B. Taylor, F. Allendorf, I. Hanski, S. Harrison, K. Ralls, D. Doak, S. Pimm, H. Possingham, R. Lacy, G. Belovsky, R. Waples, P. Hedrick, S. Haig, S. Beissinger, S. Mills, C. Walters, J. Walters, P. Wade, M. Shaffer, and D. McCullough. In addition, there will be sessions for contributed oral papers and posters. For information on the scientific program, contact Steven R. Beissinger (tel. 510-643-3038; e-mail: beis@nature.berkeley.edu) or Dale R. McCullough (tel. 510-642-8462; e-mail: mcculla@nature.berkeley.edu). For information on logistics and registration, contact William Hull (tel. 510-465-4962; e-mail: whull@cgbd.org) or visit the conference web site at http://www.cccweb.com/tws-west/pva.

LEGISLATION & CONSERVATION

This column serves to update the herpetological community on the regulatory status and protection measures implemented for rare, threatened, and endangered amphibians and reptiles. Please direct all communication to the section editor, Jeffery Demuth (postal and e-mail addresses on inside front cover).

USA: U.S. Fish and Wildlife Service: The USFWS proposes to reclassify the yacare caiman (*Caiman yacare*, also known as *Caiman crocodilus yacare*) from its present endangered status to threatened status under the Endangered Species Act. It is also proposed that the common caiman (*Caiman crocodilus crocodilus*) and the brown caiman (*Caiman crocodilus fuscus*) be listed as threatened due to similarity of appearance. The yacare caiman is native to Argentina, Brazil, Paraguay, and Bolivia, and the others occur in Mexico and Central and South America. All three taxa are listed under CITES Appendix II. A special rule is also proposed for these three species that would allow U.S. commerce in caiman skins and other parts and products under certain conditions. These conditions largely pertain to the implementation of a CITES resolution on the universal tagging of crocodilian skins. The proposals are intended to: (1) more accurately the reflect the status of the yacare caiman; (2) promote their conservation by ensuring proper management of the commercially harvested caiman species in the range countries and through implementation of trade controls; (3) relieve the burden on U.S. law enforcement personnel who must screen difficult to distinguish caiman products.

Further information may be obtained by contacting Dr. Susan Lieberman; Chief, Office of Scientific Authority; Room 750 Arlington Square; 4401 North Fairfax Drive; U.S. Fish and Wildlife Service, Arlington, Virginia 22203, USA; e-mail: Susan_Lieberman@mail.fws.gov. Comments from all interested parties should be received at the above address by 22 December 1998.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Anne Maglia or Christopher Sheil; postal and e-mail addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are listed. The Web site address is:

http://www.sisna.com/users/Herpbooks/Contents.html

Asymmetric Competition in *Rana areolata* Larval Communities

Parris and Semlitsch examined larval performance of the northern crawfish frog *(Rana areolata circulosa)*, an anuran species of particular conservation concern, at low and high population densities and under conditions of interspecific competition, with two sympatric congeners (*R. blairi* and *R. sphenocephala*), in an array of replicated artificial ponds. Their results indicated that *R. areolata* larval performance was significantly reduced in terms of larval period length and body mass at metamorphosis when exposed to interspecific competition. The authors conclude that the impact of biotic community interactions may be just as important as the preservation of critical habitat in maintaining viable populations of rare anuran species.

PARRIS, M. J., and R. D. SEMLITSCH. 1998. Asymmetric competition in larval amphibian communities: conservation implications for the northern crawfish frog, *Rana areolata circulosa*. Oecologia 116:219–226.

Effects of Silvicultural Edges on Amphibian Biodiversity

Demaynadier and Hunter studied the effects of forest edges on amphibian populations in Maine by sampling 14 species of amphibians living near the edges of various silviculture stands. Their results indicate that salamanders were more sensitive to even-aged harvest edge effects than anurans, and that the depth of edge effects were 25–35 m for the more sensitive species. Their results indicate that the effects of intensive forest management practices on amphibian communities extend beyond the boundary of the harvested stands.

DEMAYNADIER, P. G., and M. L. HUNTER, JR. 1998. Effects of silvicultural edges on the distribution and abundance of amphibians in Maine. Cons. Biol. 12:340–352.

Correspondence to: P. G. Demaynadier, Department of Wildlife Ecology, Nutting Hall, University of Maine, Orono, Maine 04469, USA; e-mail: demaynad@umenfa.maine.edu.

Salamanders Distribution and Canopy Cover

The impact of selective logging on redback salamander (*Plethodon cinereus*) populations was studied by Messere and Ducey. They collected salamanders from transects passing through forested areas and gaps one year after a harvest; they found no significant differences in the densities of salamanders in areas with different amounts of canopy cover. These results suggest that gaps formed by selective logging do not affect the distribution of redback salamanders one year after cutting.

MESSERE, M., AND P. K. DUCEY. 1998. Forest floor distribution of northern redback salamanders, *Plethodon cinereus,* in relation to canopy gaps: first years following selective logging. Forest Ecol. Manag. 107:319–324.

Correspondence to: P. K. Ducey, Dept. of Biological Sciences, State University of New York at Cortland, Cortland, New York, 13045, USA; e-mail: duceyp@cortland.edu.

Antipredator Behavior of Hatchling Snakes

To examine antipredator behaviors, the author tested the responses of hatchling pine snakes (*Pituophis melanoleucus*) to visual and vibratory stimuli. Hatchlings had been incubated at one of three temperature regimes (22–23, 27–28, or 32–33°C) and

were exposed to one of five conditions (four visual and one vibratory), testing for differences in response as a function of predator type and incubation temperature, as compared to the null hypothesis of no differences. Results indicate that emergence behavior, when undisturbed, was affected by incubation temperature, and predator type and incubation temperature affected antipredator behavior. The author found that hatchlings responded more protectively (withdrawal into tunnels) than defensively (striking), responded with less intensity to a vibration than to visual predator stimuli, responded with less intensity to a vibration than to visual predator stimuli, and required longer to respond to a head model without eyes than to all other predator types.

BURGER, J. 1998. Antipredator behaviour of hatchling snakes: effects of incubation temperature and simulated predators. Anim. Behav. 56:547–553.

Growth Rate, Adult Body Size, and Sexual Maturity in Spotted Turtles

Employing 19 years of mark-recapture data, the authors examined growth rates, adult body size, and age and size at sexual maturity of a northern temperate population of *Clemmys guttata*. Results indicate that growth rates are inversely proportional to body size, there is high variation in individual growth rates, and there are no sexual differences with respect to growth rates. Although no sexual size dimorphism exists with respect to carapace length, females were found to have significantly longer plastrons than males. In general, sexual maturity was found to be reached at larger size and estimated age (both males and females) in these animals than in the more southerly conspecifics.

LITZGUS, J. D., AND R. J. K. BROOKS. 1998. Growth in a cold environment: body size and sexual maturity in a northern population of spotted turtles, *Clemmys guttata*. Can. J. Zool. 76(5):773–782.

Sex Determination and Sex Differentiation in Amphibians

The author presents two issues that typically have been treated separately in amphibian biology—sex determination and sex differentiation. The goal of this paper is to synthesize work on these two areas of research, to place them into an evolutionary framework, and explore the interactions between them. Comprehensive reviews of Genetic Sex Determination (GSD), Environmental Sex Determination, gonadal differentiation, the roles of steroid, thyroid, and pituitary hormones, and parthenogenisis are presented. In summary, the author finds that it is likely that all amphibians display GSD, but that external factors such as temperature, physical manipulations, and exogenous hormones can influence gonadal sex differentiation.

HAYES, T. B. 1998. Sex determination and primary sex differentiation in Amphibians: genetic and developmental mechanisms. Journal of Experimental Zoology 281(5):373–399.

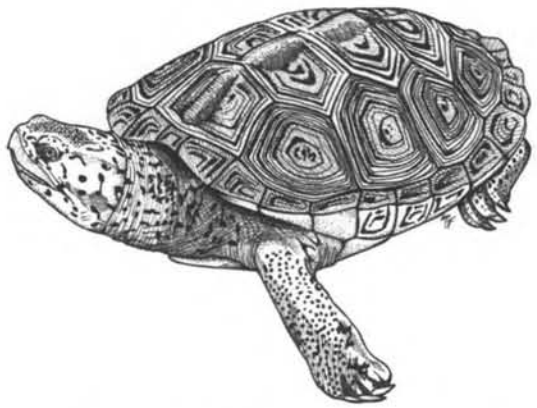
Phylogeny and Biogeography of Australian Elapids

The authors analyzed portions of the cytochrome b and 16S rRNA mitochondrial DNA genes from 19 of the 20 known Australian genera of the subfamily Hydrophiinae, as well as six of the seven Melanesian genera, a sea krait (*Laticauda*), and a true sea snake (*Hydrelaps*). Parsimony analyses led to several conclusions about these snakes: 1) the Melanesian elapids form sister groups to the Australian species, indicating that Australian radiation of these snakes came via Asia, rather than representing a relict of a Gondwanan radiation; 2) sea kraits and true sea snakes represent independent invasions of the marine environment; and 3) radiation of viviparous Australian elapids is much older than previously suggested. These analyses were unable to resolve relationships among the Australian snakes.

KEOGH, J. S., R. SHINE, AND S. DONNELLAN. 1998. Phylogenetic relationships of terrestrial Australo-Papuan elapid snakes (Subfamily Hydrophiinae) based on cytochrome b and 16S rRNA sequences. Mol. Phyl. Evol. 10(1):67–81.



Correspondence to: J. S. Keogh, Division of Botany and Zoology, Australian National University, Canberra, ACT 0200, Australia.

Conservation Genetics of Mediterranean *Podarcis*

The authors sequenced and analyzed a fragment of the mitochondrial cytochrome b gene of the endemic and endangered lizard *Podarcis atrata* of the Columbretes Archipelago (Mediterranean Spain). The population genetic structure of these lizards was analyzed as a first step to identifying evolutionarily significant units (ESU) for developing appropriate conservation strategies. Their analyses suggest that *P. atrata* from Foradada and El Lobo represent ESUs. The authors also include a brief discussion of the possibility of gene flow, from the mainland to several of these islets, which may threaten the genetic diversity of existing populations.

In the September 1998 issue of *Herpetological Review* (vol. 29, pp. 134–135), John Edwards has presented three interesting photographs, dated 1865, which he believes may be the oldest surviving portraits of living reptiles. (He mentions the photograph of a living tortoise dated 1864, but this image apparently is no longer extant.) We wish to present an earlier entry, and from a distant, and perhaps even surprising, place.

Gerard Krefft (1830–1881) was born in Germany and emigrated to Australia in 1852 (for biography, see Adler 1989, Contributions to the History of Herpetology. Soc. Study Amphib. Reptiles, Contr. Herpetol. 5:51). Among his many publications, he published the classic book, "The Snakes of Australia" (1869), and is justly regarded as the Father of Australian Herpetology. In 1864, he had the accompanying portrait made which, from the distinctive studio props, makes it clear that it was taken by the Sydney photographer, William Hetzer, who had arrived in 1850 to open a studio specializing in calotypes (a photographic method that superseded Daguerreotypes). The original photograph was discovered in an album of portraits collected by Albert Günther from his correspondents around the world, among whom Krefft was one of the most active. The album is now kept in the general library of the Natural History Museum in London. We thank the authorities at the museum, John Thackray and Vicky Street, for their assistance and permission to reproduce the photograph, which is handcolored in the original.

The live reptiles in the photograph are two diamond pythons (*Morelia s. spilotes*), an eastern blue-tongued lizard (*Tiliqua scincoides*) on the table beside the hat, and an eastern water dragon (*Physignathus lesueurii*) on Krefft's right knee. In the 1860s, Sydney had dozens of photographic studios and Hetzer may have been chosen by Krefft because he was a fellow German and, thus, with a common language, he was better able to communicate his wish to be photographed with living reptiles—something that may not have endeared Krefft to the average Sydney photographer of the day.

We await further entries in the contest to find the earliest photograph of a living reptile.

Pressure/Immobilization as First Aid for Venomous Snakebite in the United States

The pressure/immobilization method (P/I) of first aid has been used for elapid snakebite in Australia for nearly 20 years (Sutherland et al. 1979). Recently, the use of P/I for pitviper bites in the United States has become a controversial topic of discussion, especially on the Internet. We begin with an overview of snakebite first aid in the United States, discuss the place for P/I in bites by different groups of venomous snakes, and finally, advance a conservative regime for first aid. Since most venomous snakebites in the U.S. are inflicted by native pitvipers, this is emphasized in our discussion. The increasing number of exotic venomous snakes in private collections across the country has led to more bites by foreign species, especially cobras, and the utility of P/I in this setting is addressed.

Various first aid measures have been recommended over the years for pitviper bite in the U.S., including incision and suction (Jackson 1927; Jackson and Harrison 1928; Seelex 1963), constricting bands (Glass 1976; Seelex 1963), local cooling (ice application) (Glass 1976, 1981), ice water immersion or cryotherapy (Stahnke 1953; Stahnke and McBride 1966), and electroshock (Guderian 1993; Guderian et al. 1986). Immobilization by splinting has been generally favored, while more recently, suction without incisions using The Extractor™ (Extractor) (Bronstein et al. 1985, 1986) has had qualified endorsement.

Current status of controversial first aid measures.—A literature survey of 1970–1979 included 17 papers offering conflicting advice on the use of incision and suction, tourniquets, ice or ice water, splinting, exertion, and killing or catching the snake (Stewart et al. 1981). More recently, the opinions of four experts in the U.S. concerning first aid for rattlesnake bite has been published (Forgey et al. 1994).

Laboratory evidence for effectiveness of incision and suction has been conflicting (Gennaro 1963; Ya and Perry 1960; Ya et al. 1961), while ice or cold application and electroshock have not held up to lab testing (Dart et al. 1988; Howe and Meisenheimer 1988; Johnson et al. 1987; Snyder et al. 1989; Stoud et al. 1989). Incisions (Glass 1976), tourniquets (Curry et al. 1985), and ice water immersion (McCollough and Gennaro 1963; McCollough et al. 1961) have caused injury. Extractor suction (Bronstein et al. 1985, 1986) and splinting do not appear to harm and may be effective. Although splinting is generally included in many protocols, its use may sequester venom at the local site (Richard Dart, M.D., pers. comm.), and with swelling, splint wrapping may become tighter than intended (Frank Walter, M.D., pers. comm.).

The problem of recommendations based on favorable laboratory results continues. Burgess et al. (1992), using a pig-leg model,

found that a regulated pressure band at 45 mmHg effectively lowered levels of systemic venom and a sudden rise in these levels did not occur upon release. Gomez and Dart (1995) were cautious in making a general recommendation for its use as first aid based on this study. Unfortunately, the public is not likely to understand or follow the guidelines needed to use this method effectively and safely. Use of a constriction band has been recently recommended on the basis that its potential benefits in retarding systemic absorption outweigh disadvantages (Norris 1995; Norris and Minton 1995).

In general, few measures have been evaluated in a clinical setting, but specific exceptions are tourniquets for Philippine cobra bite (Watt et al. 1988), and pressure-pad/wrapping/splinting for Russell's viper bite in Myanmar (Tun-Pe et al. 1995). Unfortunately, a study of the Extractor suction device for western diamondback rattlesnake bite at a rattlesnake round-up in Texas (Bronstein et al. 1986) has only been reported as a short abstract making this clinical study difficult to evaluate. It is possible that strong suction on tissues that have undergone rapid swelling could increase local damage (David Warrell, D.M., 1998, pers. comm.). The clinical use of P/I for pitviper bites has not been reported.

First aid did not improve the outcome of victims with pitviper envenomation in other studies. In a series of 225 rattlesnake bites treated in the Los Angeles County area, first aid (incision, suction, tourniquet, cryotherapy, or any combination) did not have a statistically significant effect on envenomation severity (Wingert and Chan 1988). First aid did not modify the course of 244 pitviper bites in Colombia (Otero et al. 1992), and it may have increased local necrosis and disability in a series from the western United States (Dart et al. 1989).

In the discussion that follows, we emphasize recommendations to the general public and include special situations intended for physicians, emergency medical technicians, zoo personnel, and herpetoculturists of venomous snakes.

Severity of pitviper bite in the U.S.—The majority of venomous snakebite victims suffer no long term sequelae. However, field management and hospital treatment may actually cause more injury than the snakebite (Curry et al. 1985; Dart and Gustafson 1991; Litovitz et al. 1991). The seriousness of pitviper bites in the U.S. varies among epidemiological studies, but the following is one breakdown: dry bites 25%, mild bites 25%, moderate bites 35%, severe bites 15%, and fatal bites less than 0.5% (some of these are preventable [Hardy 1986]). (The actual percentage of dry and mild bites may be significantly higher since many males with illegitimate [interactive] envenomation do not seek medical evaluation and are not part of hospital and poison center statistics.) If these percentages are representative, most victims do well without first aid and only a small percentage will suffer local necrosis and life threatening systemic toxicity.

The Australian pressure/immobilization method.—The pressure/immobilization method (P/I) is used in Australia for the field management of elapid snakebite (Sutherland and Coulter 1981; Sutherland et al. 1979). The entire extremity is wrapped firmly with an elastic bandage and immobilized using a splint. Activity of the victim is minimized as much as possible during evacuation (Edmondson 1979). The rationale is to confine the venom to the bite site and reduce systemic absorption until arrival at a medical facility. The extremity is unwrapped only after one or more intravenous lines are established, and antivenom and mechanical ventilation capability are at hand. If the patient shows signs of significant systemic venom absorption (paralysis, shock, or coagulopathy), treatment can be instituted without delay. Laboratory and clinical studies support the use of this method in bites by Australian elapid snakes (Fulde and Smith 1984; Murrell 1981; Pearn et al. 1981). The Monash Method of pressure pad/wrapping/splinting is considered similar to P/I in this discussion (Anker et al. 1982; Tun-Pe et al. 1995).

Recent studies in human subjects of simulated snake envenomation using a radio-active colloid (ersatz venom) were treated with immediate wrapping and splinting of upper or lower extremities (Howarth et al. 1994). These measures were effective for up to 145 min, but only with the subject at rest. Even with correct and effective wrapping and splinting, those who walked for 10–25 min showed systemic absorption. This was true even if the upper extremity was involved. However, no data or literature were cited to validate this model, e.g., comparison with labeled venom to see if transit rates are comparable (Walter 1995). Problems with application of P/I in the field and evaluation of its clinical effectiveness have been commented on by Currie (1993).

Advocating pressure/immobilization outside Australia.—Pressure/immobilization has been advocated for bites by Africa's venomous snakes, including viperines and cobras, whose venom can cause necrosis (Patterson 1987; Spawls and Branch 1995). However, Blaylock (1994) criticized P/I as ineffective when used for bites in southern Africa. Sutherland (1995) disagreed because evidence was anecdotal. Blaylock (1995) replied that when the times of onset and peak of illness with and without P/I were compared, P/I offered no obvious advantage.

Absorption of Indian cobra (*Naja naja*) venom was delayed by P/I in monkeys and its use as first aid in India was recommended by Sutherland et al. (1981). P/I has also been recommended for use in viperine bite in Italy (Torregiani et al. 1991).

Advocating pressure/immobilization for pitviper bite in the U.S.—Pressure/immobilization has been recommended for pitviper bite in the United States in publications (Anderson 1994; Grenard 1994, 1998; Rosenberg 1989; Sutherland and Coulter 1981) and on the Internet (Snakebite Emergency First-aid Information, May 1998: http://www.xmission.com/~gastown/herpmed/snbite.htm). Crotaline venoms can produce significant swelling and local necrosis; effects that might increase with the use of a compressive wrap (Currie 1993; Greenland and Hoffman 1982; Holstege et al. 1997; Russell 1982). Advocates argue the benefit of delaying severe systemic effects is worth any increase in local necrosis. Monkeys injected with *Crotalus adamanteus* venom and treated with P/I had significantly reduced systemic venom levels compared to controls (Sutherland and Coulter 1981). It has also been suggested that P/I could be of benefit by restricting necrosis to a limited area (Sutherland et al. 1981).

There are few laboratory studies in animals concerning P/I and pitviper venom. Use of P/I treatment in an envenomated rat tail model resulted in increased survival rates with elapid venoms, whereas local tissue damage was increased with viperid venoms (Straight and Glenn 1985).

Warrell (1993a,b; 1995a,b) has warned that advocacy of the use of P/I in bites by viperid and elapid snakes of Asia and Africa is premature. Similar admonitions for viperid bites have been issued by others as well (Holstege et al. 1997; Norris and Minton 1995; Sullivan et al. 1995). Alternately, if the bite is potentially life threatening, e.g., large or virulent snake, multiple bites, or a prolonged evacuation time, Minton and Norris (1995) suggest P/I might buy valuable time in a trade off with potential complications.

A prospective study of 23 patients envenomated by Russell's vipers (*Daboia russellii*) in Myanmar (Burma) and treated with rubber pad compression of the bite site and immobilization (Monash Method of Australia [Anker et al. 1982]) showed the

absorption of venom was retarded in 13 patients, and 15 showed increased venom antigen levels after release of the pad's pressure (Tun-Pe et al. 1995). There was no apparent increase in local venom effects. The authors suggested the possible increased incidence of local necrosis was less serious than potential fatal complications from systemic venom effects in the field.

Pressure/immobilization should not be recommended for pitviper bite.—Pressure/immobilization should not be recommended as first aid for pitviper bite in the United States for the following reasons:

1) Local necrosis may be increased by its use because of sequestration of venom at the bite site.

2) Correct application of P/I requires knowledge of the technique and the immediate availability of appropriate materials. As with constriction bands, improper wrapping with materials at hand, e.g., torn up clothing, is possible. The pressure generated is difficult to gauge, and if wrapped loosely, it will be ineffective and if tightly, it may become a tourniquet (Warrell 1995b). There appears to be confusion by some as to whether an elastic material should be used (crepe bandage in Australia, 'Ace' wrap and 'Coban' in the U.S.) or if it should be a non-elastic (gauze) material. The latter is clearly shown in one reference from South Africa (Patterson 1987), which is contrary to the original technique (Sutherland and Coulter 1981; Sutherland et al. 1979).

3) P/I may increase the likelihood that a compartment syndrome (elevated subfascial pressures which lead to irreversible damage of major nerves [Garfin et al. 1979; Mubarak and Hargins 1981]) might develop. Although this syndrome is an uncommon complication of envenomation, the additional pressure generated by P/I when added to already mild-to-moderately elevated compartment pressures associated with some envenomations may create a compartment syndrome with resultant tissue ischemia (Warrell 1995b).

4) If evacuation requires physical exertion, P/I may become ineffective (Howarth et al. 1994).

5) Pitviper venoms often produce the immediate onset of severe pain which could be aggravated by application of P/I, and has been observed to become intolerable (R. Dart, 1997, pers. comm.).

6) A snakebite victim who is alone may find P/I impossible to apply as recommended, especially if bitten on the dominant hand (Warrell 1995b, and pers. comm. 1998).

7) In some circumstances, implementation of P/I could unnecessarily delay transport to a medical facility.

Use of pressure/immobilization in the United States.—In the United States, P/I is indicated for bites by captive Australian elapids and for other exotic elapids whose venom is known not to produce local necrosis. It may not be appropriate for bites by *Naja mossambica* and *N. nigricollis*, African spitting cobras whose venoms produce local necrosis rather than skeletal muscle paralysis (Blaylock 1994; Warrell et al. 1976). As many Asian cobras, including *N. atra, N. kaouthia, N. naja*, and *Ophiophagus hannah,* also cause a significant incidence of local necrosis (Warrell 1995b), it may be difficult to know when this might be the determining factor in the use of P/I. However, most of these Asiatic species can also cause rapid death from respiratory paralysis, so retardation of venom absorption might have greater priority than worries about the extent of necrosis, unless one is near a medical facility. Because bites from captive snakes frequently occur at locations near medical facilities, P/I could be counter productive by delaying travel.

David Warrell (pers. comm. 1998) has suggested the following approach to this problem, "The practical issue is one of balancing risks of 1) early life threatening systemic envenoming against 2) exaggeration by P/I of severe local effects which could lead to permanent morbidity. In the case of black mamba bite the risk of 1) clearly outweighs the risk of 2) and P/I is recommended. In the case of African spitting cobra bites *(N. nigricollis, N. mossambica, N. pallida,* etc.) in which neurotoxicity has never been convincingly reported in human victims, 2) outweighs 1) and, I would consider that P/I is contraindicated. The Asian cobras produce mixed effects, varying from *N. philippinensis* which causes relatively little local envenoming but rapid severe neurotoxicity (P/I definitely recommended) to *N. siamensis* and *N. kaouthia,* where local necrosis is far more common than neurotoxicity."

Envenomation by eastern and Texas coral snakes (*Micrurus fulvius*) can cause delayed respiratory paralysis (Kitchens and Van Mierop 1987) without local necrosis, and P/I may be useful in this setting. It should be noted, however, that P/I has not been specifically studied for coral snake bites (Davidson and Eisner 1996).

Certain populations of at least 10 species of rattlesnakes have venom containing phospholipase A-2 (PLA2) and/or small basic peptide (SBP) toxins (Straight et al. 1991; Weinstein et al. 1985), and their distribution, even within subspecies, is highly variable on a regional basis. Whether P/I should be considered for their bites is debatable because identification of rattlesnakes in the wild with these highly toxic (PLA2/SBP) components is problematic. Mojave toxin is found in the venom of populations of the Mojave rattlesnake (*Crotalus s. scutulatus*) in the eastern and western parts of its distribution (Wilkinson et al. 1991). Venom from some populations of the timber rattlesnake (*C. horridus*) (= canebrake rattlesnake [*C. h. atricaudatus*]) contains canebrake toxin (Glenn et al. 1994, Straight et al. 1991) which may explain some severe bites in these areas by this species (Carroll et al. 1997). P/I may be useful on a case by case basis for individuals bitten while working with rattlesnakes having confirmed PLA2 venoms, although such an application has not been studied. However, the same arguments cited against use of P/I in pitviper envenomation apply to its use for these venoms.

Prospects for a resolution.—A prospective study of P/I in human victims of pitviper bite is unlikely due primarily to the inherent variability of injury and to a lesser extent the ethical issues involved. If P/I is used by victims of their own volition, the assembled data base from patients before and after unwrapping of the extremity at a medical facility could be meaningful. However, isolated reports of outcome are less likely to shed light on the problem.

First aid recommendation for venomous snakebite.—Prevalent first aid protocols suggested for pitviper bite in the U.S. (Gomez and Dart 1995; Hardy 1992; Holstege et al. 1997; Sullivan et al. 1995; Walter et al. 1998) have been modified to reflect the above discussion:

1) Go to medical facility without delay.
2) Remain calm.
3) Remove constrictive rings, jewelry, and clothing.
4) Use the *Extractor*™ if available and using it will not cause delay.

The following are not included: incisions, constriction bands, active splinting, local cooling, electroshock, or pressure/immobilization. Although the work of Leopold et al. (1957) supports the use of passive immobilization, we have omitted it because local effects were not addressed and there has been no clinical evaluation of this method.

For bites by captive Australian elapids, P/I should be applied if a medical facility is more than a few minutes away.

Summary.—Most field treatment for venomous snakebite ap-

pears to have minimal impact on outcome. Safe and expeditious transport to a medical facility is the most important component of any first aid protocol for venomous snakebite. Pressure/immobilization should not be a general recommendation for first aid in the United States since it may worsen the predominant injuries associated with most U.S. pitviper envenomation, and has not been shown to improve outcome or reduce mortality. Application of P/I has the potential to greatly increase pain associated with pitviper envenomaton. In addition, it may be improperly applied by lay persons and is difficult to apply by a lone victim. Circumstances may exist in which P/I may be beneficial in the U.S., such as exotic, non-necrotizing elapid envenomation. However, further study in terms of outcome is needed before P/I should be widely recommended to the general public as first aid for U.S. snake bites.

Acknowledgments.—We thank Nicholas Bucknall, Richard Dart, Barry Gold, Harry Greene, Sherman Minton, David Warrell, and Wolfgang Wüster for their thoughtful comments and criticisms. The ideas expressed by authors do not necessarily represent those of the reviewers.

Our study continues the documentation of amphibian feeding ecology through characterization of prey composition and temporal aspects of feeding for two frog species. The relationship between frog size and relative prey size and number are examined to provide a better understanding of fundamental feeding strategies. Anuran food habit studies are plentiful (Christian 1982; Donnelly 1991; Flowers and Graves 1995; Jenssen 1967; Kilby 1945; Kramek 1972; Labanick 1976; Stewart and Sandison 1972), but it is difficult to directly compare any of the studies because they vary greatly in taxonomic treatment, methodology, and geographic location. Nevertheless, some general conclusions can be drawn about anuran feeding behavior. Frogs are opportunistic feeders, choosing prey from any moving object that is of an appropriate size to be swallowed. Prey choice reflects both habitat and availability (Hedeen 1970; Jenssen and Klimstra 1966; Kramek 1972; Stewart and Sandison 1972) although some anurans may develop preferences (Sweetman 1944). Insects comprise the primary pool of prey items, and similar prey items are taken by similarly sized, sympatric species (Hedeen 1970). Studies have

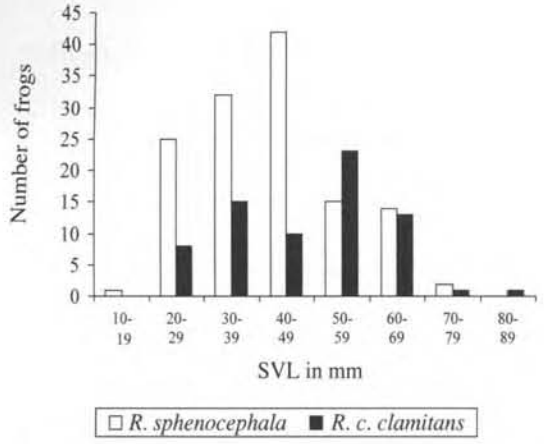

FIG. 1. Number of frogs per size class as defined by 10 mm increments of the SVL measurement.

investigated the existence of ontogenetic prey changes in anurans, testing the hypothesis that as a generalist predator grows, it will gradually switch from eating numerous, small prey items to eating fewer, larger prey items (Brooks 1964; Christian 1982; Donnelly 1991; Flowers and Graves 1995; Labanick 1976; Lima and Moreira 1993; Oplinger 1967).

The southern leopard frog, *Rana sphenocephala*, and the bronze frog, *Rana clamitans clamitans*, are similarly sized ranids found sympatrically in East Texas. The diets of these two frogs were categorized and the existence of ontogenetic prey change investigated by the correlation between the size of these frogs and the size of their prey. A second potential correlation between frog snout-vent length (SVL) and the number of prey items ingested was also tested.

Study Area.—The study site at the Forest Lake Wildlife and Forest Research Station is located four miles east of Spurger, Tyler County, Texas, USA. Owned and operated by the Temple-Inland Forest Products Corporation, it is adjacent to the Big Thicket National Preserve and consists of approximately 4050 ha of mixed pine and hardwood forests with 1620 ha of this land within the flood plain of the Neches River (Foley 1994). The area is characterized as a seasonally-flooded, bottomland-hardwood forest and is close to the western-most edge of distribution for both of these frogs (Dixon 1987).

Methods.—Frogs for this study were collected monthly from June 1995 to September 1995 coinciding with the peak emergence of recently metamorphosed frogs on site, as determined by Foley (1994). The frogs were collected from existing drift fence trap lines and manually from within the study site. Trap lines were opened 24 h prior to collection and frogs were placed into damp cloth bags for transport to the field station minimizing exposure to high temperatures and desiccation. Frogs awaiting processing were refrigerated at 14°C to slow digestion. SVL to the nearest mm was measured with vernier calipers and the weight of each frog recorded in grams using Pesola spring scales. Prey items were obtained by stomach-flushing based on the method of Legler and Sullivan (1979). We utilized a feline urinary catheter trimmed to an 8 cm length attached to a 5cc syringe. The frog's jaws were held open with a small piece of flexible 64 mm tubing for ease of handling and holding the oral cavity open. The disgorged prey items were frozen on site, then transferred to a 70% ethanol solution upon return to the laboratory. Frogs were placed in a cool, moist container and later released.

Recognizable prey items were identified to order (for insects) or to class (all other prey) using a dissecting microscope and available keys (Borror et al. 1981; Pennak 1978). Vegetation in the stomach contents was considered to be accidental "by-catch" (Hamilton 1948; Hedeen 1970; Jenssen and Klimstra 1966) and discarded. Prey items were measured using a plastic ruler to the nearest 0.5 mm. The volume of each measurable item was calculated using the formula for the volume of a cylinder ($\pi r^2 \times l$) because this shape most closely approximates that of the majority of prey items. A mean prey volume for each species, and for each size class of frog (defined as 10 mm increments in SVL) was calculated. Correlation between SVL and prey size was determined using a standard ANOVA. The SVL was also correlated with the number of prey items taken by each frog. All statistics were calculated by SPSS/PC+ version 4. 1 (1987).

Results.—Two hundred and two frogs were collected during the course of this study. Sampling success was fairly constant throughout June, July, and August (65, 52, and 73 respectively), but dropped sharply in September (12 individuals). The low number taken in September was caused by the onset of a drought which lasted 19 months. The number of frogs per size class is shown in Figure 1. Of the total number of frogs, 131 were *R. sphenocephala* ranging from 19 to 72 mm SVL and from 0. 7 to 40 g. Ninety-three of the 131 *R. sphenocephala* (71%) contained prey items with a mean of 2.1 items per frog (SE = 1.8, N = 194). Prey volumes ranged from 0.3925 to 1256 mm^3 with a mean of 70.78 mm^3 (SE = 171.6). *Rana sphenocephala* had a very high positive correlation between SVL and prey volume (F = 13.18; df = 1,134; P = 0.0004). The number of prey items ranged from 1–9 and was not significant when compared to SVL (F = 1.496; df = 1,87; P = 0.22).

TABLE 1. Percentage of prey item by taxonomic category for *R. sphenocephala* (R. s.) and *R. c. clamitans* (R. c. c.) and percentage of stomachs in which each prey category was found.

	% of Total Diet		% of Stomachs	
Prey Category	R. s.	R. c. c.	R. s.	R. c. c.
Araneae	20.5	14.78	0.27	0.32
Bivalvia	0.0	1.34	0.00	0.02
Chilopoda	2.7	2.68	0.06	0.07
Coleoptera	32.8	16.78	0.54	0.33
Dermaptera	0.5	1.34	0.01	0.03
Diplopoda	0.5	13.42	0.01	0.12
Diptera	1.1	2.68	0.02	0.05
Ephemeroptera	1.6	1.34	0.02	0.03
Gastropoda	9.2	15.44	0.15	0.18
Hemiptera	7.5	2.01	0.12	0.03
Hymenoptera	7.1	10.74	0.10	0.15
Lepidoptera	5.9	10.07	0.11	0.13
Neuroptera	0.5	1.34	0.02	0.02
Odonata	0.5	1.34	0.01	0.03
Orthoptera	8.6	3.36	0.20	0.08
Solofugae	0.5	0.00	0.01	0.00
Trichoptera	0.5	1.34	0.01	0.03
Sample size	152	136	93	60

The remaining seventy-one frogs were *R. c. clamitans* ranging in SVL from 24 to 82 mm and from 2.1 to 56 g. Sixty of the 71 frogs (84.5%) contained prey items with the mean number of items

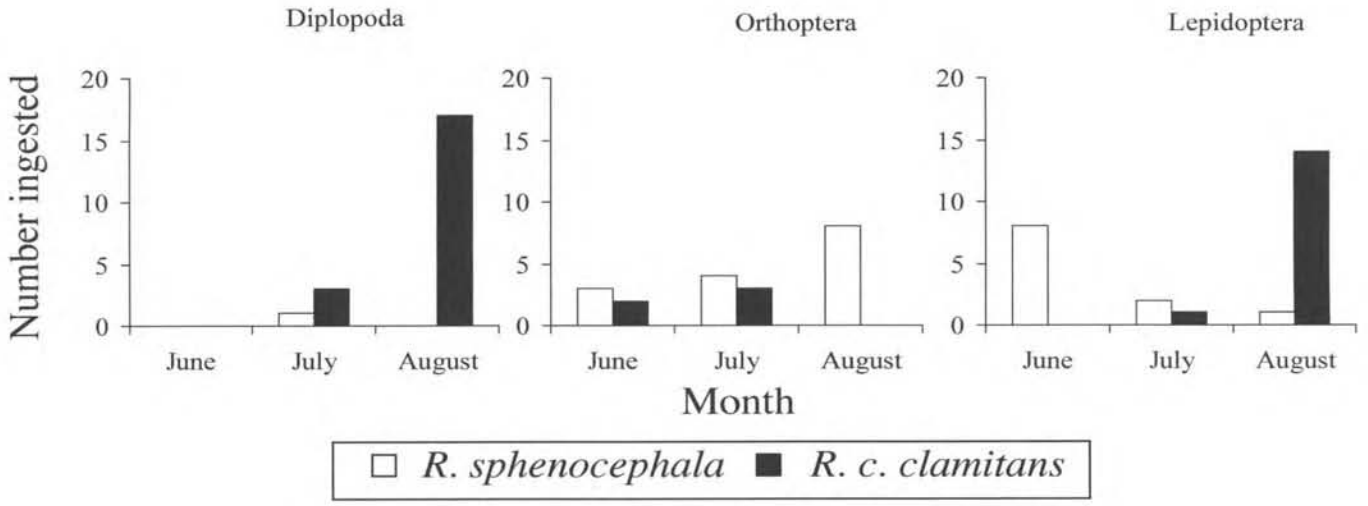

FIG. 2. Temporal variation in capture of Diplopoda, Orthoptera, and Lepidoptera by East Texas *Rana sphenocephala* and *R. c. clamitans* during June, July, and August 1995.

per frog equal to 2.5 (SE = 1.8, N = 152). Prey volumes in *R. c. clamitans* ranged from 0.19625 to 1962.5 mm^3 with a mean volume of 89.80 mm^3 (SE = 259.7). The largest size class of *R. c. clamitans* was represented by a single frog. The SVLs of the *R. c. clamitans* were positively correlated with prey volume (F = 4.7676; df = 1,144; P = 0. 03) while the number of prey items ingested, which ranged from 1–8, was not significant when compared to SVL (F = 0.7539; df = 1,57; P = 0.39).

Table 1 shows the percentage each prey category represents of the total diet and the percentage of stomachs in which each prey category was found for each species. The diets had a 60. 3% overlap; 202 items were the same out of a total of 335 recognizable prey items. Prey choices among both species consisted of six classes of invertebrates: Arachnida, Diplopoda, Chilopoda, Hexapoda, Gastropoda, and Pelecypoda. The class Hexapoda, which made up the majority of the prey, is represented by twelve orders. The most common prey items of both species were the orders Coleoptera, Araneae, and Gastropoda.

Discussion.—Several differences between prey choices are apparent when comparing the two frog species. Millipedes (Diplopoda) provide the strongest example; of the 21 millipedes eaten, 20 were taken by *R. c. clamitans*. The single specimen ingested by a *R. sphenocephala* was taken in June, while of the 20 taken by *R. c. clamitans*, 3 were ingested in July and the remaining 17 in August (Fig. 2). Of the 21 grasshoppers (Orthoptera) ingested, five were eaten by *R. c. clamitans* during June and July, while *R. sphenocephala* ate 16 over the course of the study (Fig. 2). Both of these orders provide examples of how microhabitat differences between these two species could be affecting dietary choices. *Rana sphenocephala*, like most orthopterans, is found in grassy, meadow-like areas while *R. c. clamitans* is found in moister, forested habitats corresponding to its higher rate of diplopodan ingestion. Lepidopterans, though commonly observed within the study site, appear to be more readily available in August (15 ingested) as compared to June (eight ingested) and July (three ingested) (Fig. 2).

As a final note on contents, none of the frogs in this study was found to have ingested their shed skins; the existence and importance of ingesting dead skin is debated in the general literature on anuran food habits. Nor were any vertebrates or crustaceans ingested as shown in other studies; however, this may be an artifact of sample size since both of these prey items were readily observed in the study environment.

Hamilton (1948) makes the important point that the "circumstances, season, and whims of the collector determine in large measure the recorded data of the food habits of vertebrates." This appears to be true as direct comparisons with previous studies were difficult, if not impossible. Results are reported in a variety of ways including the percentage each prey category represents of the total stomach volumes, and by the frequency each is found. The prey items are categorized by order, by family, by species, by life stage, or by habitat (terrestrial versus aquatic). We compared our results for *R. sphenocephala* to Kilby (1945). There were no directly comparable studies of *R. c. clamitans* so our results were compared to a study of *R. c. melanota* (the northern subspecies) by Jenssen and Klimstra (1966). The studies represent the distant points of the known ranges of these frogs and comparisons further support the notion of frogs as generalists. *Rana sphenocephala* had a 56% overlap in prey categories while *R. clamitans* overlapped by only 41.7%, suggesting the frogs are eating whatever prey items are available in their specific habitats rather than selecting specific quarry.

The results from our investigation support the hypothesis that larger individuals eat larger prey; however, the hypothesis that the number of prey items decreases as frog size increases was not supported. The patterns of temporal change detected in the prey base and comparisons with earlier studies further strengthens the paradigm of frogs as opportunistic feeders.

Acknowledgments.—We thank D. Foley, V. Grimley, K. Irwin, R. Nelson, D. Starkey, and J. Wisdom for assistance in the field. This work was supported, in part, by a grant from Temple Inland #RF 8861 to J. R. D.

and

MICHAEL ROBINSON
P.O. Box 21078, St. Simons Island, Georgia 31522, USA

Loggerhead sea turtles (*Caretta caretta*) are platforms for the colonization of various species of marine flora and fauna (Ernst et al. 1994). Unfortunately, much of the data on commensals and parasites associated with loggerheads is based on small sample sizes, dead turtles, and extremely broad areas of sampling (Dodd 1988). Not until Caine's (1986) research were any data available regarding loggerhead epibionts based on a large sample size of live turtles (N = 138) within the southeastern United States. Caine's (1986) study was conducted only in South Carolina and Florida, leaving a large gap for information on epibionts from *Caretta* along the Georgia coast. To our knowledge, there are only four studies which report epibionts from *Caretta* (Frazier et al. 1985, 1991, 1992; Sawyer et al. 1975). Furthermore, research conducted in Georgia can only include turtles from Camden County (Frazier et al. 1985, 1991, 1992), because Sawyer (1975) did not specify the localities from where his samples were taken.

We initiated a study to provide a comprehensive survey of the epibionts associated with nesting loggerheads in Georgia.We documented a total of 86 epibiotic species (Table 1), 76 of which had never been seen from *Caretta* in Georgia and 52 of which were unknown from loggerheads within the United States. Here, we report our data on loggerhead epibionts from five major nesting beaches in Georgia.

Our study sites were located on Blackbeard Island in McIntosh Co. (31°28.4'N, 81°13.1'W); Jekyll Island, Glynn Co. (31°03.9'N, 81°24.9'W); Little Cumberland Island, Camden Co. (30°57.2'N, 81°25.5'W); Little St. Simons Island, Glynn Co. (31°15.4'N, 81°17.2'W); and Wassaw Island, Chatham Co. (31°53.4'N, 80°58.4'W). All samples were collected during the 1997 nesting season from May to August. No samples were included from dead turtles because epibiont attachment may have occurred post-mortem and may not reflect the true nature of the observed relationship.

Sampling was conducted while the turtle was nesting or covering the nest site. All visible areas of the turtle were examined and sampled where epibiota were most prevalent. Standardization of collection sites on turtles was considered but not adopted as suggested by Caine (1986). Epibionts were collected by using a small putty knife and/or pair of forceps. Once collected, samples were placed in containers of 10% formalin or 70% isopropyl alcohol. Containers were marked with a number previously

assigned to data sheets which corresponded to each sampling attempt. Samples were only taken from tagged turtles and no turtle was sampled twice. Epibionts were sorted from the samples, counted, and identified.

Other data recorded at the time of sampling included turtle length and width, tag numbers, date, time, county, locations on the turtle where epibiota were most prevalent, and the locations on the turtle where epibionts were collected. Data sheets and samples were compiled in August and September 1997 and recorded into the Caretta Research Project/Wassaw National Wildlife Refuge database at the Savannah Science Museum.

The sites where epibionts were most prevalent corresponded to the posterior one-third of the carapace (Fig. 1). Marine turtle leeches (*Ozobranchus margoi*), however, were more common in the axial region of the turtles (Fig. 1). Also, while leeches preferred the aforementioned area, several turtles (N = 7, Wassaw Island) contained excessive loads of *O. margoi* within their ovipositors. Such obstructions of leeches were ultimately detached during egg deposition.

The relationship between marine turtles and their epibionts remains a poorly studied aspect of sea turtle natural history (Dodd 1988). The occurrence of particular epibiont species may ultimately help to clarify certain questions about sea turtle movements, habitat preference, juvenile and subadult activities, and many other aspects of their life history away from the nesting beaches (Caine 1986).

Acknowledgments.—We thank the following individuals and institutions for their help and support: Anne M. Lindsay, Randy Isbister, Karen L. Creech, Kirsten Dahlen, Rebecca Bell, Paul Hotchkin, Sarah V. Mitchell, and Alex Score (for help with epibiota collections), Robert A. Moulis and Gerald K. Williamson (Savannah-Ogeechee Canal Museum), Brad Winn and John Jensen (Georgia Department of Natural Resources), Sam Drake, John Robinette, Pat Metz, Mark Musaus, Jim Stockie and Charles Warnock (U.S. Fish and Wildlife Service), and C. Kenneth Dodd, Jr., and Jeffrey E. Lovich for providing helpful comments on the original manuscript.

The Distribution of Red-Spotted and Central Newts In Michigan

JAMES C. BALL
1083 Jewell Road, Milan, Michigan 48160, USA
e-mail: jball@ford.com

Newts have been found in many counties of Michigan since the turn of this century (Clark 1902; Ellis 1917; Evans 1915; Gaige 1915; Gibbs et al. 1905; Ruthven 1905, 1911a, 1911b; Ruthven et al. 1912; Thompson and Thompson 1912). Currently, there are four recognized subspecies of *Notophthalmus viridescens* (Collins 1997), two of which are found in Michigan (Conant and Collins 1991); the red-spotted newt (*N. v. viridescens*) and the central newt (*N. v. louisianensis*). The red-spotted newts were first described by Rafinesque (1820) followed by the description of the central newt by Wolterstorff (1914). Central newts are distinguished from red-spotted newts by their slightly smaller size, subtle differences in dorsal coloration, and the lack of black-bordered red spots (if any red spots are present they lack black borders or are incompletely bordered by black). Ruthven et al. (1928) published the first range map of the red-spotted newt in Michigan but did not distinguish between the two subspecies. To the best of my knowledge, the first range map of these two subspecies in Michigan was published by Bishop (1943). Bishop's map shows the central newt in approximately the western three-fourths of the state including the western portion of the Upper Peninsula while the red-spotted newt is found in the remaining eastern quarter of the Lower and Upper Peninsula of Michigan. In addition, Bishop's range map shows an area of intergradation between these two subspecies about one to two counties wide. Conant (1958) developed a range map that separated these two subspecies south of Saginaw Bay, but did not extend the line dividing them north of Saginaw Bay. The source of information for this map was based on museum collections and discussions with Charles F. Walker and other Michigan herpetologists (R. Conant, pers. comm.). Subsequent field guides have retained a range map very similar to that adopted by Conant in his 1958 field guide (Fig. 1; Conant and Collins 1991; Harding and Holman 1992). Recently, Harding (1997) described the red-spotted newt as residing in the drainage basin of Lake Erie and the central newt inhabiting the drainage basins of Lake Michigan and Lake Superior. Harding (1997) did not separate the subspecies in his range map for *Notophthalmus viridescens* but indicated that these two subspecies showed "a broad zone of intergradation across Michigan's Lower Peninsula and into Indiana: specimens from this area can display coloration intermediate between the two subspecies."

TABLE 1. Scores for spots and the degree of bordering by black pigment in central and red-spotted newts. See text for scoring protocol.

Location	N	Mean Spot Score ± 1 S.E.	Range	95% Confidence Interval of the Mean
Northwest Michigan	260	19.1 ± 1.0	1–77	17.2–21.1
Southeast Michigan	59	22.3 ± 2.1	1–61	18.2–26.4
Central Newts	36	8.7 ± 2.2	1–39	4.2–13.2
Red-spotted Newts	60	46.9 ± 2.7	11–120	41.5–52.2

In the Winter/Spring of 1997 I surveyed a breeding salamander population from vernal pools in a small (20 ha), isolated wooded area southeast of Ann Arbor, Michigan, and found newts with considerable variation in the number of red spots and the degree to which these spots were bordered in black. In fact, newts with no red spots and individuals with numerous black-bordered red spots were found in the same funnel trap. The newts in this population obviously are intergrades between the red-spotted newt and the central newt while the field guides at the time of this survey (Conant and Collins 1991; Harding and Holman 1992) indicated that these newts should have been primarily red-spotted newts. This led me to question the accuracy of range maps showing the distribution of these newts in Michigan. I examined museum specimens from the University of Michigan Museum of Zoology (UMMZ) and from the Michigan State University Museum (MSU); these two collections contain specimens from 55 of the 83 Michigan counties. A large number of newts from Livingston and Washtenaw counties are present in the UMMZ collection: inclusion of all the newts from these counties might seriously bias the analysis of the distribution of these newts in Michigan. Therefore, no more than 25 newts, randomly selected, from any county were used in this study. Adults and efts were examined from each county; larvae with gill structures present were not examined. Specimens were examined under a dissecting microscope and scored for the number of spots and the degree to which these spots were bordered by black pigment. A value of one was assigned to a newt that did not have any spots (a typical central newt). A numerical value was assigned to the following spot morphologies: a value of two was given to a spot with no black-borders, three was assigned to a spot with partial black-borders, and four was given to a spot with a complete black-border. Hence, a specimen with 20 complete black-bordered red spots (red-spotted newt) would be assigned a value of 80. In addition to the Michigan samples, newts from typical red-spotted newt localities (primarily Massachusetts and West Virginia; N = 60) and central newt localities (primarily Mississippi and Eastern Texas; N = 36) were also examined as control populations. Newts preserved in ethyl alcohol have lost their red pigmentation, but the spot area is much lighter than the surrounding integument and is easily discernible under a dissecting microscope. These data were analyzed using a one-way ANOVA with location as the factor and spot score as the variable (equal variance; Levene test; P = 0.1) and a Bonferroni post hoc test for multiple comparisons. Data were also analyzed using non-parametric methods and similar degrees of significance were found (statistics not shown). Data were analyzed using SPSS 7.5.2 statistical software.

FIG. 1. Distribution of central newts (A; *Notophthalmus viridescens louisianensis*) and red-spotted newts (B; *Notophthalmus viridescens viridescens*) in Michigan according to Conant and Collins (1991) and Harding and Holman (1992). Counties with open circles were included in this study.

TABLE 2. A Bonferroni post hoc pairwise comparison of the mean spot scores from different geographic locations. The mean differences between locations are presented to facilitate comparisons. Central newt specimens were from Mississippi and Texas; red-spotted newt specimens were from Massachusetts, West Virginia, New York, and Pennsylvania.

Location 1	Location 2	Mean Difference ± 1 S.E.	P-value
Northwest Michigan	Southeast Michigan	-3.2 ± 2.4	>0.99
Northwest Michigan	Central Newts	10.4 ± 2.9	0.003
Northwest Michigan	Red-spotted Newts	-27.8 ± 2.4	<0.001
Southeast Michigan	Central Newts	13.6 ± 3.5	0.001
Southeast Michigan	Red-spotted Newts	-24.6 ± 3.0	<0.001
Central Newts	Red-spotted Newts	-38.2 ± 3.5	<0.001

Geographical differences in spot scores of newts are shown in Table 1. A one-way ANOVA showed that there were significant differences in spot scores between locations ($F_{(3, 411)} = 55.5$; $P < 0.001$). A Bonferroni post hoc test for multiple comparisons of observed means is shown in Table 2. Two different Michigan populations were analyzed: newts from the west and northwest part of Michigan and the southeast section of the state (Fig. 1). There was no significant difference in spot scores from the southeast corner of Michigan (mean = 22.3; Table 2) compared to the newts from the west and northwest of Michigan (mean = 19.1). The northwest Michigan newts (mean = 19.1) scored significantly greater values than the central newts (mean = 8.7) and significantly smaller values than the red-spotted newts (mean = 46.9). Likewise, the southeastern Michigan newts (mean = 22.3) scored significantly greater values compared to central newts (mean = 8.7) and significantly smaller values than the red-spotted newts (mean = 46.9). As expected, central newts (mean = 8.7) scored significantly lower values than red-spotted newts (mean = 46.9). Because the mean spot scores for the Michigan newts were not significantly different from each area, the data from both regions were combined and the mean for the entire Michigan population was determined. The mean spot score for Michigan newts (mean = 19.7 ± 0.9) is closer to the score for central newts than it is for red-spotted newts (midpoint between red-spotted and central newt = 28). This suggests that Michigan newts are more similar to central newts than red-spotted newts.

These results suggest that all newts from Michigan are intergrades between these two subspecies and that the area of intergradation between these subspecies is likely to be on the order of states not counties. Minton (1972) came to a similar conclusion suggesting that "much of Indiana is a zone of intergradation" between these two subspecies. I recommend, therefore, that future range maps for these two subspecies of *Notophthalmus viridescens* show a wide range of intergradation that encompasses at least Michigan and possibly Indiana.

Acknowledgments.—I thank Greg Schneider and Arnold Kluge of the University of Michigan Museum of Zoology, and Laura Abraczinskas of the Michigan State University Museum for access to their preserved collections. I especially thank Jim Harding for his many helpful discussions and encouragement for this and other projects. Leo Perron's presence is always felt in the field and his encouragement is gratefully acknowledged.

A Bite from the Rear-Fanged Colubrid *Psammophis phillipsii*

PHIL SENTER*
Department of Biology, Box 97388, Baylor University
Waco, Texas 76798-7388, USA

**Present address: 473 Ruff Crossing, McGregor, Texas 76657, USA*

Although bites from most species of rear-fanged colubrid snakes are harmless to humans, the venom of a few species can be dangerously toxic. Bites from the rear-fanged colubrid genera *Dispholidus* and *Thelotornis* can be fatal (Broadley 1957), and bites from species of *Boiga* may cause severe symptoms (Fritts et al. 1994).

Significant symptoms have also been reported from bites of some species of *Psammophis*. Broadley (1959) reports that a bite from a large *P. sibilans sibilans* caused local swelling, which was gone in 48 h. Fitzsimons (1970) reports that a *P. s. sibilans* bite may cause "excruciating pain, swelling, nausea, cold sweats etc. for some days after a bite." Broadley (1983) reports that a *P. phillipsii* bite may cause "local pain, swelling, inflammation and nausea, which passes off within about 48 hours."

The taxonomic status of the aforementioned species and subspecies of *Psammophis* was revised by Broadley (1977). Unfortunately, as Spawls and Branch (1995) note, this opens to question the identity of each individual snake whose bite contributed to the published descriptions of bites from *Psammophis*. Broadley does not cite case histories in his 1983 publication, and the reader is not told whether the individual *Psammophis* whose bites contributed to the description therein, were identified before or after Broadley's (1977) revision of the genus. If researchers are to know which symptoms to expect from particular species of *Psammophis*, then new case histories need to be collected, and the snakes involved need to be identified per Broadley's (1977) revision.

On 7 January 1989, I sustained a bite from a 114 cm *Psammophis* that had been collected in Monrovia, Liberia. The snake was identified as *P. phillipsii* using Hallowell's (1844) original description of the species, Villiers (1950; as *P. sibilians phillipsii*), Hughes and Barry (1969), and Broadley (1977).

The snake bit the tip of my right index finger and chewed for 60 s before releasing its bite. I then lay down and propped up my right hand with pillows. By 5 min 30 s after the snake ceased to chew, the site of the bite exhibited swelling, a slight purple color, and a burning, stinging throb. An ice cube was applied to the proximal half of the finger 7 min 15 s after the snake released its bite. By 14 min after the bite, the entire finger was red, swollen, and difficult to bend. At 35 min post-bite, the ice was removed; burning persisted at the bite site. One hour and 30 min after the bite, the finger was still swollen, and pain persisted at the bite site. Nine hours after the bite, the finger had almost returned to normal size (it had been half again its usual diameter at the height of the swelling). Twenty-one hours after the bite, the finger had regained its usual size and color, but retained stiffness and soreness at the bite site and at the joints. No symptoms persisted after 48 h. The bite caused neither nausea nor cold sweats.

On 20 June 1986, I caught a 41 cm *P. phillipsii* in Yekepa, Nimba County, Liberia. The snake bit my fingers and chewed, presumably to facilitate venom injection. No noticeable symptoms resulted. However, the snake regurgitated a skink soon thereafter; it is possible that the snake had spent most or all of its venom on the skink, and had little or none left with which to envenomate me.

Acknowledgments.—I thank John Anderson for pointing out the large *P. phillipsii* to me at the American Cooperative School in Monrovia. Jayne Cawthon transported it home for me. I thank Len Laughridge for tape-recording and timing my comments on the progress of the symptoms, for providing the ice, and for the use of his dorm room during the recording of the symptoms.

Prolonged Oviductal Egg Retention Arrests Embryonic Growth at Stage 34 in Captive *Calotes versicolor*

RAJKUMAR S. RADDER
BHAGYASHRI A. SHANBHAG*
and
SRINIVAS K. SAIDAPUR
Department of Zoology, Karnatak University, Dharwad 580 003 India

** Author to whom correspondence should be directed*

The retention of eggs in the oviduct in oviparous lizards is well documented (DeMarco 1993; Shine and Guillette 1988). During the period of egg retention, embryos continue to develop up to certain stages (modal embryo at oviposition is stage 30; N = 38 species) depending on the species (DeMarco 1993). When gravid lizards do not oviposit in captivity, they die because of stress and/or death of the embryos *in utero* (Doughty 1996; Muthukkaruppan et al. 1970). *Calotes versicolor* is a multiclutched, agamid lizard known to breed from May–October in Dharwad, India (Shanbhag and Prasad 1993a). Oviposition and hatching occurred at stages 27 and 42, respectively (staging scale according to Dufaure and Hubert 1961), in captive *C. versicolor* and the interval between successive stages was 2–4 days (Muthukkaruppan et al. 1970). Unreported was the number of days taken for oviposition in captive gravid females.

A previous study of captive *C. versicolor* has shown that following induction of ovulation using pregnant mare serum gonadotropin (PMSG), fertilization of eggs and normal development of the embryos occur in the absence of males, thereby suggesting utilization of sperm stored in the oviduct (Shanbhag and Prasad 1993b). Upon termination of the experiment after 15 days, examination of the eggs revealed embryos at stages 27–28, the stages at which oviposition is known to occur. The findings suggest that oviductal egg retention time in *C. versicolor* is about two weeks (Shanbhag and Prasad 1993b).

In our laboratory, we have undertaken reproductive studies of captive *C. versicolor*. We maintained 11 gravid females (SVL 9.2–11 cm; body mass 33–49 g) collected from areas around Dharwad, Karnataka, India (15°17'N 75°3'E) during May, the early part of the breeding season. The presence of oviductal eggs was confirmed by palpation of the abdomen. The lizards were kept in wire mesh cages (90 x 120 x 120 cm). Each cage had a sand bed of about 9 cm, a water dish, and a few bricks and dry sticks for shelter. Live cockroaches or grasshoppers were provided *ad libitum* on alternate days. Every morning the cage bed was inspected for oviposited eggs.

None of the 11 wild-collected gravid females laid eggs during the two weeks following their capture. Four of these were necropsied to assess the embryonic development of the oviductal eggs. Of these, one had eggs with embryos at stage 27, others had embryos of stages 28, 31, and 32, respectively. These observations suggest that each individual among these four lizards had ovulated at different times and therefore had embryos at different stages of development. The remaining seven lizards were autopsied after 32 (two lizards), 42 (three lizards), 52, and 78 (one each) days in captivity. All seven lizards had eggs with healthy embryos at stage 34. The adult females were healthy and active and displayed no signs of ill health. Three lizards even showed the preparation of a second clutch of eggs as evidenced by the presence of vitellogenic follicles in the ovary.

In *C. versicolor*, hatching occurs between 65–71 days when the eggs containing embryos with stage 27 are removed from oviducts and incubated at ambient temperature. It takes about 4–6 days for all the eggs in a clutch to hatch (unpubl. observations). The present study shows that captive *C. versicolor* can retain oviductal eggs for well over two months (78 days), a period approximating the time required for total embryonic development (oviductal egg retention period + duration of incubation before hatching), i.e. 80 ± 5 days. However, the development of embryos in retained eggs is arrested at stage 34. Previous studies have reported death of captive lizards that were unable to oviposit and in such cases the embryos were found in advanced, though unspecified, stages of development (Doughty 1996; Muthukkaruppan et al. 1970).

Egg retention in turtles is believed to be an adaptation that facilitates delayed nesting/oviposition when unfavorable environmental conditions prevail or when suitable nest sites are not available (Ewert 1985; see also Plotkin et al. 1997). The arrest of embryonic development at stage 34 in captive *C. versicolor* may be a strategy to overcome the increasing demands of the growing embryos on one hand and avoid possible mortality of the female holding oviductal eggs for long periods possibly due to the lack of suitable nesting sites.

Acknowledgments.—This work is supported by a grant from DST(SP/SO/C-16/96), and partly by UGC SAP II Grant, New Delhi.

A variety of physiological and genetic studies has shown the utility of blood samples in sea turtle research (e.g., Bickam et al. 1980; Bowen 1995; Gross et al. 1995; Owens and Morris 1985; Wibbels et al. 1990). The endangered status of many sea turtle populations has prompted the development and use of nonlethal methods for obtaining blood samples over the past two decades (Bentley and Dunbar-Cooper 1980; Dutton 1996; Owens et al. 1978; Owens and Ruiz 1980). In past studies, blood has been sampled from a variety of vessels including the heart (Dozy et al. 1964; Frair 1977), the carotid artery (Berkson 1966), the dorsal cervical sinus (Owens et al. 1978; Owens and Ruiz 1980) and the rear flipper (Dutton 1996). Of these, the dorsal cervical sinus approach has proven to be reliable for obtaining blood from juveniles and adults, and is in widespread use. Owens et al. (1978) and Owens and Ruiz (1980) initially described the location of the dorsal cervical sinus (i.e., paired vessels running lateral to the spinal column along the dorsal aspect of the neck), but a detailed anatomical description of these vessels has not been reported. The ability to obtain blood from hatchling sea turtles has been reported in a few studies (Dutton 1996; Gross et al. 1995; Fitzsimmons 1996; Fitzsimmons et al. 1996), and sampling from the bilateral cervical sinus of hatchling *Caretta caretta* was described in one previous study (Bennet 1986). The availability of safe and reliable methods for obtaining hatchling blood samples would be of value to studies addressing subjects such as sex ratios and population genetics. The purpose of the current study is to provide a comprehensive evaluation and detailed description of safe and practical methods for obtaining blood samples from hatchling sea turtles. The study extends the findings of previous studies by 1) evaluating different sampling locations, 2) sampling from three different species of cheloniid sea turtles, 3) providing a detailed description of the methodology, and 4) evaluating sampling techniques both in the laboratory as well as on the nesting beach.

Blood Vessels Used for Sampling.—A variety of locations along the dorsal surface of the neck were examined in order to identify optimal sites for obtaining blood. Two optimal locations were identified (see detailed description of each below). Although cardiac puncture has been used to obtain blood from hatchlings in a previous study (Gross et al. 1995), it was not evaluated in the current study because it is more invasive than sampling from blood vessels in the neck.

Blood Sampling Equipment.—Blood samples were collected with 1 cc tuberculin syringes equipped with 1.3 cm, 25 gauge needles. The syringes were heparinized using a concentrated solution (3.2 mg per ml of sterile water) of sodium heparin (ovine, Sigma Chemical Co.). A volume of approximately 0.2 cc of the solution was taken into the syringe, allowed to coat the walls of the syringe, and was then expelled. Numerous syringes were heparinized in advance and then placed on ice until they were used later the same day. In the case of genetic/molecular studies, anticoagulants such as acid citrate dextrose solution B (ACD-B) or EDTA are preferred over heparin since they result in less DNA degradation (Dutton 1996; Gustafson et al. 1987).

Blood Sample Volume.—Due to the relatively small size of hatchlings, only a small amount of blood can be sampled safely. The blood volume of turtles has been estimated to be approximately 5–6% of body weight (Schmidt-Nielsen 1994; Thorson 1968). In general, a maximum of 10% of blood volume can be sampled safely. Therefore, the maximal amount of blood that can be taken safely can be estimated by multiplying the weight of a hatchling by a factor of approximately 0.005. As an example, in the case of a hatchling with a weight of 20 g, a maximum of 100 µl of blood should be sampled.

Blood Sample Processing.—For hormone studies, blood samples are transferred to 0.6 ml microcentrifuge tubes and spun at approximately 6000 RPM in a small microcentrifuge for 5 minutes. The plasma is decanted into separate 0.6 ml microcentrifuge tubes and frozen. For genetic/molecular studies, the cellular fraction (or the entire blood sample) can be placed on ice, frozen, or transferred to lysis buffer depending on the specific application (Dutton 1996; Gustafson et al. 1987).

Evaluation of Blood Sampling Techniques in the Field and in the Laboratory.—Blood sampling techniques were evaluated during four field studies and one laboratory study. A total of 845

hatchling blood samples were successfully collected: 80 from *Caretta caretta* from the Archie Carr National Wildlife Refuge (ACNWR), 197 from *C. caretta* from Hutchinson Island, Florida, 57 from *Chelonia mydas* from the French Frigate Shoals in the Hawaiian archipelago, 385 from *Eretmochelys imbricata* from Buck Island Reef National Monument, U.S. Virgin Islands, and 126 from *C. caretta* hatched in the laboratory from eggs collected at ACNWR. At several of these study sites, sampling was conducted on the nesting beach and samples were placed on ice until they could be processed. In the field studies, hatchlings were released after sampling and all appeared active. In the laboratory study, hatchlings were maintained in aquaria and observed for several days following sampling. No obvious change in activity levels was noted and no mortality was associated with the sampling.

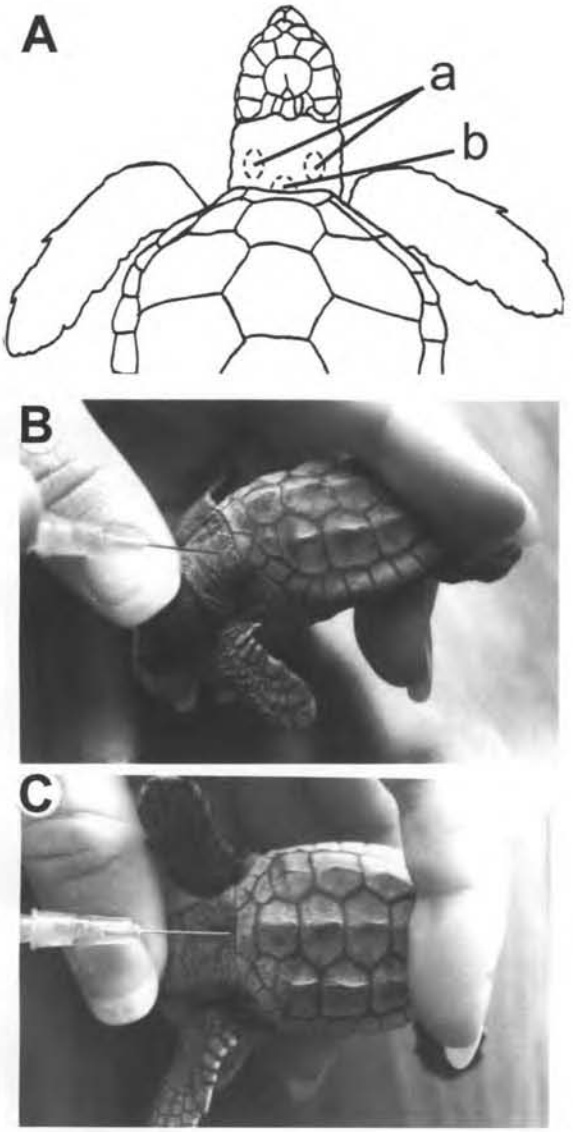

FIG. 1. Blood sampling techniques for hatchling sea turtles. A) Optimal sites for sampling blood. (a) Area for inserting needle to sample from dorsal cervical sinus. (b) Area for inserting needle to sample from alternate sampling location located under nuchal scute. B) Example of technique for sampling from dorsal cervical sinus. C) Example of technique for sampling from under the nuchal scute.

Blood samples were consistently obtained from two locations on the dorsal portion of the neck. The first was the dorsal cervical sinus (see sampling location "a" on Fig. 1A and Fig. 1B). These are a pair of blood vessels located lateral to the spinal cord on both sides of the neck (Owens et al. 1978). Additionally, a second blood sampling site was identified along the midline of the neck, just under the nuchal scute of the carapace (see sampling location "b" on Fig. 1A and see Fig. 1C). Both sampling locations were used successfully to obtain samples from *C. caretta* and *E. imbricata* hatchlings. The dorsal cervical sinus was used successfully to obtain samples from *C. mydas* hatchlings, but the second sampling site was not evaluated in this species. A detailed methodology for obtaining blood samples from both of these sampling locations is provided below.

In the laboratory we were able to obtain blood samples from 100% of the hatchlings (N = 126), although multiple sampling attempts were necessary for most hatchlings. In the field, it was desirable to collect more hatchlings than were needed for the blood sampling. In that way, blood sampling was usually attempted a maximum of two times for each hatchling (e.g., once from the left cervical sinus and once from the right cervical sinus). If no blood sample was obtained, the hatchling was released and sampling was attempted on a new hatchling. In general, a blood sample could be obtained from 2 of every 3 hatchlings using a maximum of two sampling attempts. Obtaining blood samples from hatchlings is more difficult than sampling from juveniles or adult sea turtles, but the diligent use of the techniques described below should allow one to successfully obtain blood samples from most hatchlings.

Detailed Description of Blood Sampling Methodology.—The neck of the hatchling should be swabbed with a disinfectant such as 70% ethanol and then allowed to dry. To position the turtle for sampling, the hatchling is held in one hand using the index and middle fingers (Fig. 1). The hatchling is positioned with its head pointed downward in an effort to fill blood sinuses in the neck. The thumb is used to slightly lower the head, thus extending the neck. Blood sampling from the dorsal cervical sinus is best accomplished by inserting the needle at a relatively steep angle (Fig. 1B), lateral to the midline of the neck and several millimeters from the carapace (see sampling location "a" on Fig. 1A). The needle is inserted approximately 0.25 to 0.5 cm into the neck and a slight upward pressure is placed on the syringe plunger to generate a vacuum. If no blood is obtained, the needle is pushed slightly deeper or withdrawn slightly, while maintaining a vacuum. It is apparent in some cases that the needle may be inserted in the correct location, but the sinus is temporarily collapsed. Even without moving the needle, blood flow can be intermittent, particularly in response to muscle contractions in the neck. Therefore, it is advantageous to hesitate for a short period before moving the needle position because of lack of blood flow. If blood is not obtained, the needle can be removed and then inserted in a similar location on the opposite side of the neck (i.e., switch from right to left cervical sinus or vice versa).

The second bleeding site is on the midline of the neck, just under the nuchal scute of the carapace (Fig. 1C; also see location "b" on Fig. 1A). The needle is inserted at a relatively shallow angle (Fig. 1C), at a depth of approximately 0.25 cm, and vacuum is applied as described previously. If blood is not obtained, the needle can be moved slightly inward or withdrawn slightly while maintaining a vacuum. Inserting the needle too deeply at this location should be avoided since it can result in the needle contacting the vertebrae. In general, this site was utilized when difficulty was encountered in obtaining blood from the dorsal cervical sinus.

Regardless of which sampling site is used, blood sampling is optimally accomplished when the surface of the hatchling's neck is dry. In that situation, blood coming to the surface after the needle is removed forms a bead that can be aspirated into the syringe. As much as 50 µl of blood can be obtained in this fashion, thus representing a significant volume of blood from a hatchling. Once an adequate amount of blood is obtained, the thumb is used to push the hatchling's head in a slightly upward position, thus compressing the dorsal portion of the neck and preventing blood loss after the sample is taken.

The results indicate that the techniques described above provide a safe and practical means of obtaining hatchling blood samples from at least three species of cheloniid sea turtles. These methods may be applicable to hatchlings of all sea turtle species, as previous blood sampling studies of adults and juveniles suggest the dorsal cervical sinus is a common feature of all sea turtles, including *Dermochelys coriacea* (Rostal et al. 1996). In fact, blood samples have been collected from the dorsal cervical sinus of *D. coriacea* hatchlings (D. Rostal, pers. comm.).

Acknowledgments.—The completion of this study was made possible through ongoing sea turtle research conducted by the National Marine Fisheries Service, Honolulu Laboratory, Hawaii, and the National Park Service, Buck Island Reef National Monument, U.S. Virgin Islands. Support for the project was provided, in part, by the Mississippi-Alabama Sea Grant Consortium under Grant #NA56RG0129.

Backpacks for Lizards: A Method For Attaching Radio Transmitters

JONATHAN Q. RICHMOND
Department of Biology 0116, University of California, San Diego
La Jolla, California 92093-0116, USA

Present address: Department of Biology, San Diego State University
San Diego, California 93281-4614, USA
e-mail: richmond@sunstroke.sdsu.edu

Radio telemetry provides a reliable method for studying various aspects of habitat use in horned lizards (Fisher and Muth 1995). Perhaps the most difficult aspect of utilizing radio telemetry in these small, cryptic lizards is finding a suffcient technique for attaching a radio transmitter. Fisher and Muth (1995) proposed a backpack design for attaching a radio transmitter to the flat-tailed horned lizard *Phrynosoma mcallii*. However, we experienced difficulty with this design in telemetry studies of a larger species, the coast horned lizard *Phrynosoma coronatum*. This difficulty stemmed from the construction and materials of the harness, designed for adult *P. mcallii* (62–81 mm SVL, Stebbins 1985; 11.0–25.0 g, Fisher and Muth 1995). Adult *P. coronatum* (62–100 mm SVL, Stebbins 1985; 21.0–53.0 g, N = 33, mean = 34.5 g, Suarez et. al., unpubl. data) easily destroyed the harness material through normal daily activity. To alleviate this problem, we constructed a harness similar to the Fisher and Muth design (1995). However, our backpack has fewer components, fewer attachment points, and provides a sturdier design for the larger *P. coronatum*.

A PD-2 transmitter with an external whip antenna (Holohil Systems Ltd.) was used in our study. The transmitter (including battery and investment acrylic) weighs 3.25–3.50 g, and is powered by a lithium camera battery (Li 75). Battery life ranges from 4.5 months to 6 months, and can be adjusted according to specific electronic configurations. Transmitter signals were received on an LA 12-Q portable radiotelemetry receiver with a three element Yagi antenna made by AVM Instrument Company Ltd.

The harness is constructed by taking an ordinary bicycle innertube and cutting it to resemble the letter "U" (Fig. 1A). The horizontal portion of the "U" forms the region of the harness where the transmitter is fastened, and is approximately 20 x 20 mm. The vertical portions of the "U" form the straps, and are approximately 3–4 mm wide and 80–100 mm long. These dimensions are easily adjusted to the size of the lizard. The harness weighs approximately 1.0 g without the transmitter attached.

Innertubes commonly are coated with a substance that prevents drying and cracking of the rubber, but it also interferes with gluing the transmitter to the rubber. The innertubing should be washed with soap and water to remove the protective coating. Exposure tests demonstrated that the washed material maintains its elasticity and construction throughout the life of the transmitter battery (4.5–6 months). The transmitter is attached to the backpack by lightly sanding the acrylic coating, then gluing (cyanoacrylic glue) one side of it to the 20 x 20 mm portion of the U-shaped backpack. The antenna should be pointing in the opposite direction of the straps since the straps are slung over the shoulders of the lizard.

Once the transmitter is fastened to the harness, several dabs of glue are placed on the underside of the 20 x 20 mm square. The entire pack is then placed on the lizard's back, making sure that the straps are pointing anteriorly (Fig. 1B). It is imperative, at least with horned lizards, to position the backpack such that the transmitter does not contact the occipital horns (at the rear of the head), yet is as far forward on the back as possible. If one were to draw a line perpendicular to the spine and even with the forelimbs, the front of the transmitter is positioned at this point. The straps are then placed over the shoulders, crossed on the chest, pulled through the axilla region of the opposite leg, and glued to the top of the 20 x 20 mm section of the backpack (Fig. 1C). Excess strap material is removed. Glue is applied between the straps where they cross on the venter, as well as a small dab between the crossed straps and the lizard's skin. This prevents the pack from shifting off the midline. The straps should not be pulled too tightly around the neck and shoulders. However, horned lizards commonly inflate the thorax and abdomen as a defense posture, so strap tension must compensate for this extra volume. Ideally, the straps should have a snug fit when the lizard's thorax is not inflated.

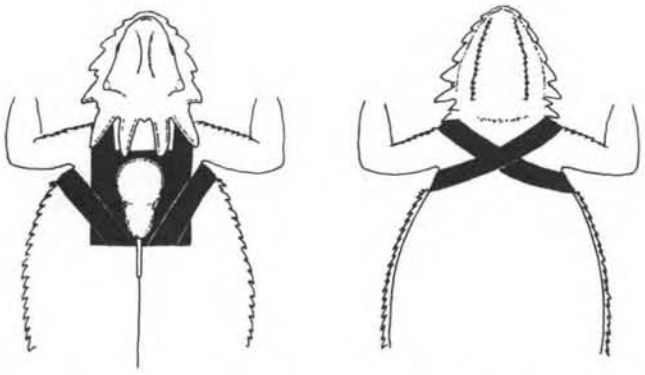

FIG. 1. (A) The U-shaped harness without the radio transmitter attached. (B) Dorsal view with the transmitter and harness attached to the lizard. (C) Ventral view with the shoulder straps crossing over on the chest.

Because horned lizards rely on crypsis to avoid predators (Pianka and Parker 1975), the backpack and transmitter were painted with acrylic paint to match the skin color of the lizard. Colors were easily mixed and matched in the field, and water can be used as a solvent as long as the paint is wet. The backpacks were painted after they were attached to the lizards because clean surfaces are required for proper glue adhesion. With age and wear, the camouflage paint and the backpack takes on a more cryptic appearance.

Horned lizards have remarkably mild dispositions; therefore, backpacks were easily assembled and attached to the lizards in the field. In most cases, *P. coronatum* resumed normal activity minutes after attaching a backpack. Feeding, locomotion, burying, and breeding appeared unaffected by the unit. The total mass of the backpack, about 4.5 g, constitutes as little as 12% of the total body mass in large adults. Oviductal clutches of female *P. coronatum* are reported as high as 24% of total body weight (Pianka and Parker 1975), thus our design weighs considerably less than a typical clutch of eggs. Of the 28 lizards fitted with this harness (April 1996–present), only one presumably detached from a lizard. All other backpacks remained attached for the duration of the transmitter battery life.

Acknowledgments.—I thank Andrew Suarez and Ted Case for giving me the opportunity to work on this project, and to John La Bonte for field assistance. Mark Fisher and one anonymous reviewer provided useful comments on the manuscript. This study was funded by grants from the Metropolitan Water District of Southern California, Southwestern Riverside County Multi-species Reserve Management Committee – RFP No. 128, and the U.S. National Science Foundation DEB-9610306, awarded to Ted Case and Andrew Suarez.

Intracranial Stereotaxic Surgery on Reptiles with External Tympana

MICHAEL S. GRACE
Department of Biology, Gilmer Hall, University of Virginia
Charlottesville, Virginia 22903-2477, USA
e-mail: msg5y@virginia.edu

Stereotaxic positioning devices allow accurate mathematical placement of electrodes and similar devices for survival surgeries in inaccessible (for example intracranial) locations (see for example Feigenbaum 1985; Ruby et al. 1996). For accurate and precise animal positioning in stereotaxic surgery, the subject must be rigidly mounted in a standard manner. Reptiles with external tympana present difficulties with both of these problems. Small animal stereotaxes are designed for animals with ear canals; earbars inserted into ear canals provide two points in a 3-point mount, and with the toothbar, provide accurate lateral (square) positioning of the head. Reptiles such as iguanid lizards cannot accept earbars in the traditional manner without damage to the tympanic membranes. Therefore, these animals cannot be held rigidly in typical small animal stereotaxic devices. Because the position of rodent ear canals varies little among individuals of the same species, ear canals also provide a means for standardized positioning of the rodent head in the device. As such, it is difficult to standardize head position of reptiles with external tympana.

Greenberg (1982) presented in very limited fashion a method of mounting *Anolis carolinensis* in a small animal stereotax using elastomeric dental material as a bridge between earbars and the tympana. Here I describe in detail a modification of this method

that provides rigid, accurate, and precise positioning of reptiles in the stereotax. I also discuss methods of anesthesia, and provide a safe and acceptable method of anesthetizing iguanid lizards. I have successfully used these techniques for effective stereotaxic survival surgeries on numerous *Iguana iguana*.

A Kopf Model 900 small animal stereotax (David Kopf Instruments, Tujunga, California, USA) was used with a Kopf Model 960 electrode manipulator (Fig. 1). Both standard rat earbars (Kopf Model 957, tip angle approximately 20°) and optional 45° tip earbars (Kopf Model 955) were tested. Ultimately, 45° tip earbars were selected as standard, because the greater tip angle decreased chances of tympanic membrane perforation. Three major modifications were made to the stereotax: (1) a cushioned bite plate was mounted to the tooth bar, (2) the straight nose bar was bent into a 90° angle and cushioned, and (3) a vinyl polysiloxane cushion was added to the tips of the earbars.

The bite plate (Fig. 2) was made by cutting a "T" of sheet aluminum (1 mm thick), the base of which matched the width of the tooth bar. The plate was then coated (approximately 1 mm thick) with freshly-prepared vinyl polysiloxane dental impression material (Reprosil Type 1 high viscosity, Dentsply International, Milford, Delaware, USA). After the dental material cured, the coated plate was attached to the flat upper surface of the toothbar with two stainless steel screw-driven pipe clamps. The nosebar was also modified for iguana surgery by bending it into a 90° angle inverted "V", and then covering it with a tight-fitting length of Tygon tubing to form a cushion.

Dental impression material is also used to modify the stereotax earbars. Small batches of freshly prepared dental material are applied to the tips of the earbars. When the earbars are advanced toward the tympana and the dental material allowed to cured, the impression material conforms to the lizard's head contours, providing a rigid but harmless and easily removed attachment between the animal's head and the stereotax earbars.

With the modified stereotax, surgeries were performed on chemically-anesthetized animals. I tested ketamine HCl (100 mg/ml; Ketaset, Fort Dodge Laboratories, Ft. Dodge, Iowa, USA) as an anesthetic agent for *Iguana iguana*, and found that the effective dose was greatly lowered by administering to animals whose body temperature was 35–37°C. Under these conditions, 90 mg ketamine/kg body weight given subcutaneously, intramuscularly, or intraperitoneally effectively induced anesthesia (loss of righting reflex, and loss of flinch response to a pinch of lateral body skin). It should be noted, however, that ketamine injected subcutaneously may cause tissue damage in iguanid lizards. After subcutaneous injection, a deep blue color appeared around the injection site within one hour of injection, and lasted for at least two weeks.

Greenberg (1982) used hypothermia to immobilize *Anolis carolinensis* for placement of electrolytic lesions with the aid of a stereotax. Hypothermia has also been used by many others, but generally today is considered to be an ineffective anesthetic agent (Bennett 1996), immobilizing the subject but failing to prevent noxious sensory input. Hypothermia may also be damaging. For example, Northcutt and Butler (1974) reported retinal axon degeneration following experimental hypothermia in *Nerodia sipedon*. Even so, hypothermia continues to be used by some investigators (Tosini and Menaker 1995). In my preparations, Ketamine HCl (administered at 90 mg/kg to warmed *Iguana*) provided at least 30 minutes of complete anesthesia, allowing ample time for surgical setup and procedures.

When animals display full anesthesia, the upper jaw is placed flat onto the biteplate, and the angled nosebar clamped firmly

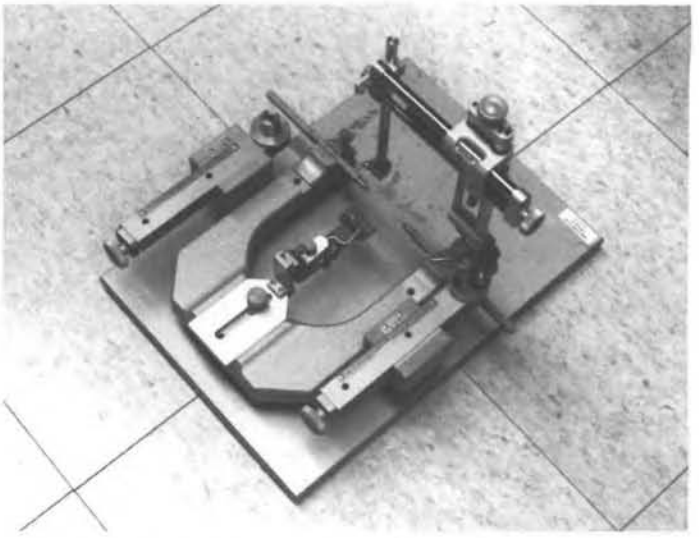

FIG. 1. The Kopf Model 900 small animal stereotax. Note the biteplate/nosebar apparatus in the center of the instrument. Electrode carrier(s) mounts to the positioning device lateral to the biteplate/nosebar apparatus.

down onto the bridge of the animal's rostrum. For accurate stereotaxic surgery, the animal's head must be square in the stereotax (the rostro-caudal axis of the head must be parallel to the longitudinal track of the electrode manipulator). To set this angle, 20° tip angle earbars are placed in the stereotax, and advanced equally to points near an identifiable feature on the animal's head (I use the anterior margin of the tympanum). The nosebar is loosened, and the animal's head angle set such that reference points are equidistant from each earbar tip. The nosebar is then re-tightened, and numeric position of the earbars is noted with their tips placed 1mm from the tympanic membranes.

Dental impression material base and catalyst are then mixed 1:1 for 30–45 seconds, and a small (approximately 6 mm diameter) sphere of material is applied to the tip of each earbar. Reprosil has a working life of approximately 2 minutes, so it must be prepared after the animal has been anesthetized and clamped onto the biteplate. The earbars are then slowly advanced toward the tympana until they have reached the previously determined

FIG. 2. Modified biteplate/nosebar apparatus (left) for reptile positioning, and original instrument (right) designed for rodents. Note that in the modified apparatus a cushioned biteplate (arrow) has been mounted to the toothbar, and the nosepiece has been bent into a 90° inverted "V" and cushioned with a length of tight fitting silastic tubing (arrowhead).

setpoint. The dental impression material is allowed to cure for approximately 6 minutes before beginning surgery. Reprosil contains toluene and methylene chloride, so repeated exposure of surgical subjects and personnel to uncured product should be avoided.

The modified stereotaxic procedure described here has been used successfully on *Iguana iguana*, SVL <7 cm to >25 cm, for precise and repeatable intracranial placement of electrodes for electrolytic lesioning. This stereotax will also accommodate animals much larger than those tested, and the modular nature of the modified Kopf system makes it extremely convenient and cost-effective for surgeries on multiple types of animals. I commonly perform surgeries on both iguanid lizards and rodents, using a single stereotax, two toothbar/nosebar pieces, and two sets of earbars. One toothbar/nosebar apparatus remains in unmodified form for rodents, while the other is modified for use on reptiles. The setup can be modified from rodent to reptile use in less than 1 minute by replacing the entire rodent toothbar apparatus with the modified biteplate apparatus, and replacing the two earbars. Reprosil dental impression material forms a cushion to prevent tooth damage on the biteplate. It can be cleaned easily, and also can be easily removed and reapplied if necessary. Reprosil also forms a rigid connection between earbars and the subject's head while preventing damage of external tympana. Following surgery it is easily and completely removed without harm to the animal.

Reptiles are important model systems for neurobiological investigation, particularly in comparative analyses (Foster et. al. 1994; Grace et al. 1996). My research group performs stereotaxic electrolytic surgery on *Iguana iguana* hypothalamus and forebrain with the goal of defining neural organization of the circadian timing system in vertebrate animals. The stereotaxic technique described here is useful for any intracranial survival surgery requiring accuracy and precision, and can be used directly on anapsid and many diapsid reptiles (but with snakes, for example, it is not possible to accurately position and attach earbars), as well as on anuran amphibians.

A reliable method for collecting sufficient quantities of venom from the Duvernoy's gland of colubrid snakes was described by Rosenberg et al. (1985). Anesthetized snakes are intraperitoneally injected with a saline solution of pilocarpine HCl (5 mg/ml; Sigma Chem. Co., St. Louis, Missouri) at a dosage of 0.1–2.0 mg/100 g body weight. Pilocarpine is a parasympathomimetic muscarinic agonist that stimulates the discharge of secretory products from the lumen of salivary glands (Mahr et al. 1980). This method also was employed successfully by Stuart (1998) for collecting salivary and Duvernoy's secretions from 23 taxa in five families of snakes (dosage 2.0 mg/100 g body weight) and by Hill and Mackessy (1997) for collecting Duvernoy's secretions from 14 colubrid species (dosage 0.75 mg/100 g body weight). None of these authors reported adverse effects, except for Hill and Mackessy (pers. comm.) who noted mortality in a few specimens that were in poor body condition and not feeding prior to treatment; otherwise they injected pilocarpine into snakes without apparent harm. Both Rosenberg et al. (1985) and Stuart (1998) injected individuals repeatedly (up to ten times) without later complications such as weight loss or cessation of feeding.

The collection of large quantities of venom from the gila monster, *Heloderma suspectum*, and the beaded lizard, *H. horridum*, has been problematic. Similar to opisthoglyphous colubrid snake venoms that flow from one to three ducts of the Duvernoy's gland to the base of grooved maxillary teeth, the venom from the infralabial gland of *Heloderma* discharges from multiple ducts to the base of grooved teeth in the lower jaw. The method of collecting venom used by the Miami Serpentarium Laboratories (Punta Gorda, Florida) involves inducing a lizard to bite a neoprene rubber disc, turning the animal onto its back, and pipetting the secretions as they flow down the plate (N. Haast, pers. comm.). Stuart (1998) inserted flexible plastic tubing (15 cm long; 12 mm outer diam, 8 mm inner diam) over the front teeth of an adult *Heloderma suspectum* perpendicular to the longitudinal axis of the body. The lizard repeatedly compressed the tube with its jaws, and venom dripped from the front of the mouth onto a watchglass placed under the chin. Approximately one ml of venom was collected within ten minutes.

Loeb (1913) subcutaneously injected 21 adult *Heloderma suspectum* (body weight not reported) with 0.1 grain (= 6.48 mg) of pilocarpine. The pilocarpine increased the duration and quantity of the venom secreted by 3–4 fold compared to methods not using pilocarpine. Three animals died after being injected once per day for three successive days.

We injected intraperitoneally a healthy, young adult *Heloderma suspectum* weighing 650 g with 2.0 mg of pilocarpine HCl (Sigma)/100 g body weight, the same dosage used by Stuart (1998) for snakes. The animal was cooperative and was not anesthetized during the procedure. Within three minutes of injection, venom and saliva began flowing copiously from the lower jaw. Approximately one ml of fluid was pipetted from the mouth within five minutes of the initiation of secretion. After ample venom had

been collected for the intended analysis, the lizard was returned to its habitation; oral secretions flowed continuously from the lower jaw until the animal expired 18 h later.

Electrolytic imbalance after such prolonged secretion may have contributed to the death of this animal. Drowning on salivary secretions has been reported in a number of species injected with high doses of the muscarinic agonist slaframine (Hagler and Croom 1989), but was ruled out in *Heloderma* by a necropsy (NCSU Teaching Hospital Report #97-0124). However, approximately 10 ml of a slightly opaque fluid was found in the stomach, and was presumed to be venom and saliva that had been swallowed. Whether or not this fluid contributed to the death of the animal is unknown.

A greater number of trials would strengthen the present study. However, because of the conservational status of *Heloderma*, currently it is not feasible to test enough individuals to construct an LD_{50} curve for the effect of pilocarpine on this taxon. Nevertheless, it can be concluded that *Heloderma* is more sensitive to pilocarpine than are snakes. Assuming that Loeb (1913) used animals similar in size to the one of the present study, his *Heloderma* perished after three injections of half the dosage tolerated by snakes over ten consecutive doses (Stuart 1998). Also, the single *Heloderma* used in the present study succumbed to one injection of the dosage given to snakes; this animal was a young one and probably smaller than those used by Loeb.

Loeb (1913) mentioned one instance of administering 2.1 grains (= 136.08 mg) to eight *Heloderma* that presumably survived (data not reported). The dosages cannot be calculated exactly without body weights but assuming the body weight of his animals to be 650 g (the weight of our animal), this injection corresponds to 0.23 mg/kg, slightly more than ten times the dosage of pilocarpine that proved lethal in the present study. These discrepancies may be explained by Loeb (1913) using a lower purity of pilocarpine than that presently available. The pilocarpine used in the present study was >99% pure as tested by thin layer chromatography (Sigma Chem. Co., St. Louis, Missouri). Alternatively, methodological differences may have affected results. Loeb (1913) injected subcutaneously; we injected intraperitoneally.

To examine the effects on another species of lizard, a 900 g *Iguana iguana* was injected intraperitoneally with 2.0 mg pilocarpine/100 g body weight. Salivation began within three minutes. The animal became lethargic, convulsed, and perished 35 minutes later. However, subsequent injections of the same dosage of pilocarpine to four juvenile iguanas (47, 86, 97, and 270 g) stimulated salivation without obvious adverse effects.

It is unclear whether pilocarpine induces changes in the composition of venom (Weinstein and Kardong 1994). Rosenberg et al. (1985) found an increase in water content and a decrease in protein concentration of colubrid Duvernoy's secretions induced by pilocarpine compared to levels in secretions obtained by merely rinsing the oral membranes. They did not believe that there was much influence of the drug on the nature of the secretory proteins. Similarly, Marmary et al. (1987) did not find changes in protein composition of rodent parotid glands stimulated by pilocarpine. Fox and Loeb (1913) found that the drug induced zymogen degranulation of the duct cells of *Heloderma* venom glands in a manner similar to that reported for salivary glands. Loeb (1913) found that venom obtained with pilocarpine was as toxic in rats and guinea pigs as that obtained without pilocarpine. We found that the *Heloderma* venom obtained with pilocarpine was mixed with considerably more saliva than that obtained by the bite-collection methods described above, as evidenced by higher mucus content and significantly greater amylase activity (Stuart 1998). Although the secretions obtained by pilocarpine may be a better representation of the total oral secretions that coat prey that is being swallowed, contamination by saliva may confound precise analysis of the composition of the infralabial venom of *Heloderma*.

There are also interspecific differences in the effects of pilocarpine in mammals. Marmary et al. (1987) reported a 3–4 fold greater pilocarpine-induced salivary flow in mice than in rats. Similarly, cattle and sheep appear to differ in their responses to pilocarpine. Gurnsey et al. (1980) reported that cattle can sustain intramuscular injections of up to 2.0 mg pilocarpine/kg body weight, without their ad libitum intake of food being affected. For subcutaneous injections that threshold for sheep was only 0.4 mg pilocarpine/kg body weight (Bird et al. 1991). The mixed agonist properties of pilocarpine seem to induce different physiological responses even among closely related taxa, and, hence, may be tolerated by snakes but lethal to lizards. Studies concerning the pharmacological characterization of muscarinic receptors in non-mammalian species are not extensive (Jones and King 1995), and caution is advised when transferring protocols across taxa.

Acknowledgments.—We thank Nancy Haast and Stephen Mackessy for unpublished data, Felicia Nutter for performing an autopsy on the *Heloderma* specimen, and Arizona Game and Fish for donating the *Heloderma*. This research was approved by the Institutional Animal Care and Use Committee of North Carolina State University (#95-075).

Slevin's bunch grass lizard (*Sceloporus slevini* fide Smith et al. 1996; formerly *S. scalaris slevini*) was first known in the United States from high altitudes. The earliest record for the country (Van Denburgh 1896:341), under the name of *Sceloporus scalaris*, was from 9500 ft in the Huachuca and Dragoon Mountains, and by 1922 (Van Denburgh 1922:268–273) the species still was known only from "above seven or eight thousand feet" in the Dragoon, Huachuca, and Santa Rita Mountains. By 1954 (Stebbins 1954:234–235) its known range had been extended to the Chiricahua Mountains, but still only above 8000 ft. By twelve years later (Stebbins 1966), however, the species had been recorded from "lowland" localities at "Empire Valley, 11 miles northeast of Sonoita, 4300 ft., Santa Cruz Co., Arizona, and upper Animas Valley, 10 mi. east of Cloverdale, 5200 ft., New Mexico."

In June 1987, RLH found the species to be very abundant at low altitude about the remains of a burned corral 3.3 mi. east of Elgin, on the Sonoita Plain (between the Huachuca and Santa Rita Mts.), Santa Cruz Co., Arizona, at 4800 ft. The lizards hid under small boards scattered widely on the ground, in lieu of their usual refuges of bunch grass, which was missing in that vicinity due to heavy grazing by cattle. As reported by Bock et al. (1990) and Smith et al. (1990), those authors also observed numerous *S. slevini* at the same place, and found it to be very common elsewhere on the Sonoita Plain, especially on the Audubon Research Ranch, ca. 8 km SSE of Elgin. Indeed, it was by far the most common lizard where grazing was limited or prevented completely. Much the same observations were repeated in July 1990, after the preceding publications appeared. Ballinger and Congdon (1996) have recorded the strongly deleterious effect of grazing on the same species in the nearby Chiricahua Mts.

In summary, it is an established fact that *S. slevini* occurred rather widely at least from about 1965 to recent times in grasslands at relatively low altitudes (4300–5400 ft.) in southeastern Arizona and southwestern New Mexico. Whether it was present at such altitudes before that time is not known.

In June and August 1997, a number of the authors walked a total of about 9 miles of grassland each month, half on the Audubon Research Ranch (5000–5200 ft. elev.), where no cattle grazing has occurred for three decades (since 1968), and half on adjacent grazed ranchland. In earlier years we would have seen several hundred *S. slevini* with that much search (Bock et al. 1990), but on these occasions none was seen. The burned corral debris east of Elgin, where both Smith and Holland had previously found the species to be abundant, no longer was inhabited by it, although there were a few *Cnemidophorus* much as before. On 12–13 September 1997, after grass cover became luxurious due to ample rainfall, CEB and JHB again thoroughly surveyed areas on the Research Ranch where the species was formerly abundant, and found none. The lizards therefore probably were not estivating during the dry months, because we would have expected them to become active after the 1997 rains and subsequent plant growth.

The apparent proximate cause for the essentially complete disappearance of the species at low altitudes was a severe drought persistent over the past two years (Fig. 1). Predation may be enhanced by the drought and the concurrent stunting of the bunch grass that serves as cover for the lizards, but that alone cannot be the cause, for the population at the burned corral west of Elgin would not be more exposed to predation during the drought than prior to it. Other lizards and snakes appeared subjectively to be somewhat reduced in number, but they seemed not to be severely affected. *Sceloporus slevini* has clearly been affected far more than any other observed reptile species.

Presumably the species survives at high altitudes with little if any attrition due to drought, inasmuch as the latter would be much attenuated or absent there. However, refugia exist even at lower altitudes, as observed by JAR, who on 23–29 March 1997 backpacked along trails through numerous habitats southeast from the town of Patagonia, Santa Cruz Co., Arizona, through the Canelo Hills and across the Huachuca Mts. to the Coronado National Memorial. He observed 18 *S. slevini* in three areas (~5 mi. E Patagonia; Redrock Canyon near the Canelo Hills; and Scotia Canyon on the west side of the Huachuca Mts.), mostly in ungrazed, grassy habitats in close proximity to water. Several were observed on grazed land, but always where thorn scrub protected the grass from being grazed, or where rocks or debris provided adequate cover. Away from these havens, no other *S. slevini* were seen.

The reason for the differential susceptibility of *S. slevini* to drought perhaps lies with its presumed adaptation as a species to relatively high altitudes. Since periodic extended droughts have no doubt occurred for centuries in the southwest, it is quite likely that the range of *S. slevini* ebbs and flows with them, recovering between episodes of severe drought by repopulation from refugia

scattered across the lowland range of the species. The former, wide-ranging population on the Sonoita Plain therefore may recover in the next few years from its present decimation. On the other hand, those lowland populations may well be more threatened by drought today than they might have been in earlier times, because of the combined impacts of drought and livestock grazing. Now so much of the original habitat is unsuitable because of grazing that (a) most of the refugia are gone, and (b) the populations are so small and fragmented that they are highly vulnerable to extirpation.

Such a scenario is, however, conjectural. The current fact is that *S. slevini* has a greatly reduced lowland population on the Sonoita Plain at the present time, and therefore is a species of concern that should be monitored over the next several years. The extent of decimation, if any, in adjacent areas remains to be determined. Termination of the drought may enhance recovery where losses have occurred.

HERPETOLOGICAL HUSBANDRY

A Safe, Easy-to-Use Tool for Assist-Feeding Small Reptiles and Amphibians

R. MICHAEL BURGER
Department of Herpetology, San Antonio Zoo
3903 North St. Mary's Street, San Antonio, Texas 78212, USA

Small reptiles and amphibians often can be difficult to manipulate during handling and attempts to assist feed or medicate orally. A technique often used to open the mouths of small lizards (*Anolis* spp., *Uroplatus* spp., etc.) involves tapping on their snouts. However, many diminutive squamates, anurans, and salamanders inevitably need an implement forced between their jaws in order to successfully open their mouths. Spatulas, credit cards, forceps, plastic spoons, plastic wedges cut from deli cups (Barker 1982; deVosjoli 1996) as well as other items all work to some degree depending on the size of the specimen involved. These items can be cumbersome because of size or dangerous due to sharp edges when dealing with extremely small animals.

A tool that has been successfully used in a wide range of neonate, small, or delicate reptiles and amphibians has been a plastic guitar pick. Relatively inexpensive and available at most music stores, the pick is available in several sizes, thicknesses, and compositions. The thin Fender® guitar pick (Fender Musical Instrument Corporation, Scottsdale, Arizona, USA) works particularly well and has smooth, tapered edges. The utility of a lightweight guitar pick allows one to hold a small animal in one hand, slowly insert the guitar pick with the other, and easily follow with a food item or medication tube without the risk of the guitar pick falling out due to its weight or cumbersome size. It does take practice (as is the case with almost any technique); once inserting the food item or tube, one must carefully excise or swipe the guitar pick away from the mouth. Because of the triangular shape of a guitar pick, swallowing the pick is impossible with an animal whose gape is less than the width of the pick. This tool has been used successfully with *Phyllomedusa hypochondrialis, Rhacophorus reinwardtii, Agalychnis callidryas, Ambystoma* sp., *Uroplatus henkeli, Atheris ceratophorus, Lampropeltis* spp., *Elaphe* spp., *Rhinocheilus lecontei, Spilotes pullatus, Calabaria reinhardtii, Tropidophis* sp., *Ungaliophis continentalis, Corallus caninus, C. hortulanus, Morelia viridis*, and *M. spilota variegata.*

Age at sexual maturity is one of the most important aspects of population dynamics. The longer individuals take to start breeding the longer the generation length and the slower the population rate of increase (Caughley 1977). However, there is little information about age at sexual maturity in crocodilians. Age at sexual maturity ranges from 2.5 years for *Crocodylus palustris* in captivity to possibly 35 years for *Crocodylus niloticus* in the wild (Ferguson 1985). Magnusson and Sanaiotti (1995) report that *Caiman crocodilus crocodilus* attains sexual maturity at 5–6 years of age in the Brazilian Amazon, but they note that growth rates vary among habitats and individuals. Moulton et al. (in press) suggest an asymptotic snout-vent length (SVL) of 87–107 cm, with an estimated age range of 8.6–15 years for *Caiman latirostris* female first reproduction in a mangrove habitat of southeastern Brazil.

This report documents the first production of second generation (F_2) broad-snouted caimans in captivity. Genealogy and other information about these animals is available in the Regional Studbook for the species (Verdade and Kassouf-Perina 1993). The broad-snouted caiman captive breeding program is maintained by the Department of Animal Sciences of the Escola Superior de Agricultura "Luiz de Queiroz," University of São Paulo, located in Piracicaba, São Paulo (22°42.557'S, 47°38.246'W). This region presents a tropical climate with wet summers and dry winters (Simielli 1993). Although temperatures can get below 10°C during the winter and above 30°C during the summer, monthly average temperatures range from 16.8°C in June to 24.7°C in February, with only four months (May–August) below 20°C (Ometto 1991).

The caimans were maintained under natural temperature conditions since they hatched. During the first six years of life they were maintained in walled pens of 64 m^2 (ca. 2.7–10.7 m^2 per individual) with a 60 cm deep cemented pool of ca. 24 m^2 (1.0–4.0 m^2 per individual). They were then transferred to and maintained in a fenced area of 120 m^2 (20–30 m^2 per individual) with a one-meter-deep cemented pool of ca. 30 m^2 (5–7.5 m^2 per individual). Nesting shelters, consisting of an approximately 4 m^2 partially walled area, adapted from Bustard (1975), were provided and successfully utilized by the females.

Age at first reproduction was approximately 10 years (Table 1). Clutch size ranged from 36 to 44 with an average of 40.25 eggs per clutch. Incubation period ranged from 85 to 89 days with an average of 86.5 days. Eggs were incubated as described by Verdade et al. (1992a) with hatching success of 40–86%, and averaging 67% (see Table 2 for a summary of reproduction). Hatchlings were raised as described by Verdade et al. (1992b), and presented a low mortality rate (0.75%) at seven days post-hatching.

A New Technique for Artificially Incubating Loggerhead Sea Turtle Eggs

CHAD L. CROSS
Department of Biological Sciences, Old Dominion University
Norfolk, Virginia 23529-0266, USA

JOHN B. GALLEGOS
FLORENCE G. JAMES
and
SARA WILLIAMS
U.S. Fish and Wildlife Service, Back Bay National Wildlife Refuge
4005 Sandpiper Road, Virginia Beach, Virginia 23456-0286, USA

The loggerhead sea turtle (*Caretta caretta*) is a recurrent visitor to the southeastern coastline of Virginia (USA). Female loggerheads generally nest on a two to four year cycle, and construct from one to six nests during each breeding season (Dodd 1988; Ehrhart 1979). Nesting in southeastern Virginia usually occurs in June or July. The resulting eggs incubate for 60–65 days before hatching (Dodd 1988).

U.S. Fish and Wildlife Service personnel at Back Bay National Wildlife Refuge (BBNWR) in Virginia Beach, Virginia conduct daily patrols along a 16–24 km stretch of beach from mid-May through August. Because of very narrow beaches and large numbers of visitors, nest failure because of human and tidal impacts would be high; therefore, nests are excavated and removed to a remote area of BBNWR, placed in cylindrical, predator-proof cages (35.5 cm diam, 78.7 cm height) constructed of meshed hardware cloth over a wooden frame, and buried at the same depth as the original nest. This technique has worked satisfactorily for a number of years; however, the late production of nests in August (one in 1995, two in 1996) raised concern that allowing nests to remain in situ through October would result in low hatching success from low subsurface sand temperatures during the incubation period. We believed that mimicking the natural nest environment would be the best solution. Artificial nests allow eggs to be buried at a natural depth and provide space for an adequate amount of sand to be placed around the nest. The entire artificial nest must be transportable to a warmer environment.

We used a large, plastic tree planter pot for the artificial nesting chamber (67.3 cm deep, with a top diameter of 76.2 cm narrowing to 52.1 cm at bottom). Several holes were drilled through the pot sides and bottom to facilitate aeration and drainage. The pot was lined with burlap to stop loss of sand through holes.

The nesting chamber was easily transported to a nest site via an all-terrain vehicle equipped with a small trailer. The bottom of the pot was then lined with 15–20 cm of damp sand from the original nest. The predator-proof nest cage (described above), with intact nest inside, was excavated and placed into the pot using heavy rope or straps that were originally buried around and under the nest cage. The eggs themselves were not excavated or otherwise disturbed. The remainder of the pot was filled to within 8 cm of the top with moist sand from the nest cavity (Fig. 1). The nesting chamber was then towed back to an enclosed, heated building.

The temperature of the nesting chamber was kept at 27–29°C by maintaining the room temperature at ca. 25°C, and was supplemented by using 3–4 small hood 100-watt lamps clipped to the sides of the trailer. Nest temperatures at egg level were monitored daily with a deep soil probe. Lamp number and location can be adjusted to maintain desired temperatures.

This technique was successful for the three late nests at BBNWR during 1995 and 1996, with hatching success of 94%, 88%, and 42%. Hatchlings were released on the beach in order to imprint on the natal nesting site, then collected and transported out to the Gulf Stream where they were released. This technique should prove valuable to researchers and conservationists requiring an inexpensive, easily maintained artificial nesting chamber for incubating late-season eggs.

FIG. 1. Nesting chamber used to artificially incubate loggerhead eggs. The nest cage, straps used to lift the nest cage, thermomenter, and heat lamps are visible. See text for full description of the nesting chamber.

Acknowledgments.—We thank R. Muller of the USCOE for his consistent support over the years. We also thank all of the permanent and

seasonal staff at BBNWR whose perserverance and dedication has made our efforts successful. We owe a special debt of gratitude for the technical support provided by K. A. Phelps. BBNWR field personnel were partially supported by the U.S. Army Corps of Engineers, Norfolk, Virginia. We thank J. Geiger, D. Stewart, and J. Robinette for helpful comments on earlier drafts of the manuscript.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 29, Number 1 (March 1998).

CAUDATA

AMBYSTOMA OPACUM (Marbled Salamander). **ALBINISIM**. Herein we report three partially albino *Ambystoma opacum* larvae. Two were discovered from the same vernal pool in Tiverton, Newport County, Rhode Island, USA (BD, JB) during 1988. A third specimen was found during March 1997 from a vernal pool in Lyme, Connecticut, USA (HG).

On 31 March 1988, an albino *A. opacum* larva (46 mm TL) was captured in 16.5 cm of water at 1535 h. The ambient temperature was 13.5°C; water temperature was 12°C. A second albino larva (50 mm TL) was captured on 6 May 1988 in 30.5 cm of water at 1200 h; ambient temperature and water temperature were 15.5°C and 14.5°C. This specimen was photographed at the capture site and released.

The coloration of both living animals appeared identical. Alive, the larval integuments were transparent with a yellowish cast; eyes appeared normally pigmented except that the pupils were pink, and the visceral organs, major blood vessels, and developing cranium were clearly visible through the integument. The external gills were flushed orange-red from blood. Preserved, the first larva appeared chalky-white with a slight hint of its former yellowish cast. This animal was catalogued in the American Museum of Natural History (AMNH 130240). Using definitions from Harris (1970. Bull. Maryland Herpetol. Soc. 6:21–22), both specimens were partial albinos, possessing integumentary xanthophores and orbital melanophores.

On 27 March 1997, another albino *A. opacum* larva was discovered in a vernal pool in Lyme, Connecticut. The coloration of this specimen was similar to that of the Tiverton larvae except the gills were yellowish and showed no red coloration from its blood, the eyes were slightly darker yellow than the integument, and most of the tail musculature was devoid of color and appeared white. The animal was placed in a jar, photographed, and returned to the pool. Color slides of this larva were sent to AMNH.

Albinism in *A. opacum* has been documented twice previously, once from Maryland (Harris, *op. cit.*) and once from Mississippi (Dyrkacz 1981. SSAR Herpetol. Circ. No. 11). To our knowledge, this is the first documentation of albinism for *A. opacum* in New England.

We thank Dr. Wang Yong and Charles W. Painter for their comments on this manuscript.

GYRINOPHILUS PORPHYRITICUS (Spring Salamander). **COLORATION**. Although many *Gyrinophilus porphyriticus* spend much time underground, making use of subterranean springs and caves (Bishop 1947. Handbook of Salamanders. Comstock, Ithaca, New York. 535 pp), albinism has been reported in only one population (Brandon and Rutherford 1967. Am. Midl. Nat. 78:537–540; Dyrkacz 1981. SSAR Herp. Circ. 11). On 1 May 1997 in Chenango County, New York, USA, we found an albino (leucistic) larval *G. porphyriticus* (66 mm SVL, 50 mm TL) at the emergence of an underground spring ca. 550 m elev. The individual had a completely pigmentless integument, gills pink with hemoglobin, and normally pigmented eyes. A total of 15 larvae and adults, all normally pigmented, were found at the same site over a 15 day period. The specimen is deposited in the SUNY Cortland Bowers Natural History Museum (97-101PKD).

Submitted by **CARMEN FERRIERO**, **SCOTT MILLER**, **MATTHEW CHAPMAN**, and **PETER K. DUCEY**, Department of Biological Sciences, State University of New York at Cortland, Cortland, New York, 13045 USA.

PLETHODON HUBRICHTI (Peaks of Otter Salamander). **ALBINISM**. Albinistic and leucistic salamanders in the genus *Plethodon* have been recorded for *P. cinereus* (Harris 1968. Bull. Maryland Herpetol. Soc. 4:57–60; Pauley 1974. Redstart 41:104), *P. dorsalis* (Thurow 1955. Copeia 1955:62–63), *P. glutinosus* (Piatt 1931. Copeia 1931:29), and *P grobmani* (reported as *P. glutinosus*, Highton 1956. Copeia 1956:75–93).

On 26 May 1996, we found a leucistic, gravid, adult female *P. hubrichti* (53 mm SVL, 111 mm total length, 1.9 g) in the George Washington and Jefferson National Forest, 960 m, 7.0 km SE Arcadia (79°33'55", 37°29'38"), Botetourt County, Virginia, USA (Fig. 1). Integumentary pigment was completely lacking, although she had normally pigmented eyes. She was found in a six-year-old clearcut of striped maple (*Acer pennsylvanicum*) and red oak (*Quercus ruber*) saplings. We maintained the female in captivity to obtain reproductive data but despite efforts to induce feeding, she died about 10 weeks after capture. This is the first record of the leucistic phase of albinism in this endemic Blue Ridge Mountains species. The specimen is catalogued in the Virginia Museum of Natural History (VMNH 8086).

FIG. 1. Leucistic albino *Plethodon hubrichti*.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 29, Number 1 (March 1998).

CAUDATA

AMBYSTOMA LATERALE (Blue-spotted Salamander). **COURTSHIP and EGG LAYING BEHAVIOR**. *Ambystoma laterale* is a spring breeder found from Nova Scotia to New England and throughout the Great Lakes region (Vogt 1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, Milwaukee, Wisconsin. 205 pp.). Few studies on the courtship behavior of this species have been published (Arnold 1977. *In* D. H. Taylor and S. I. Guttman, eds., The Reproductive Biology of Amphibians, pp. 141–183. Plenum Press, New York). Observations on the courtship and egg laying behavior of *A. laterale* were conducted during March–April of 1991, 1992, and 1995 at an ephemeral pond in Waukesha Co., Wisconsin, USA. These observations confirm the pattern reported by Kumpf and Yeaton (1932. Amer. Mus. Novit. 546:1–7) and Storez (1969. J. Herpetol. 3:87–95) and provide additional observations on courtship.

Salamanders were collected in pitfall traps, or during nocturnal migration. In the laboratory, they were maintained at 15–20°C in a 37.9-liter aquarium containing moist soil and bark for cover. Salamanders were not segregated by sex. Courtship and egg laying observations were made in a 75.7-liter aquarium with a gravel substrate, plastic plants, twigs, leaves, and rocks to stimulate natural conditions during two weeks following capture. Approximately 25 cm of dechlorinated or pond water at 20°C was used for all the trials. Courtship and egg laying behaviors were observed under light and dark conditions using red and white light. Females were placed in the tank with either one or two males. The courtship description follows Salthe's (1967. Copeia 1967:100–117) division of salamander courtship into five stages: 1) awareness and overtures, 2) capture of female, 3) initiation of spermatophore deposition, 4) spermatophore deposition, and 5) insemination of female.

Five courtships were observed for *A. laterale* in the laboratory: three with one male and one female, one with two males and one female, and one with two females and one male. Courtship rituals were variable, but all had recognizable characteristics.

The first stage, awareness and overture was brief. The first awareness by the male of the female, or vice versa, seemed to be chemically dependent, as both sexes seemed to be tasting the water while moving about the tank. The nudging behavior that followed awareness became critical to the male's recognition of the sex of his partner. When a male approached another animal he would direct his snout to the side region between the fore and hind limbs. Simultaneously, the male would prod his snout against the other animal's side and/or cloacal region. This behavior was directed equally to both sexes when present but soon became more intense and directed solely toward the female. This short nudging process usually lasted 30–45 s and was followed by the second stage capture of the female.

Capture of the female began by the male amplexing with the female. Amplexing usually lasted 1–2 minutes. The capture of the female consisted of three parts as described by Storez (*op. cit.*). In the initial clasp the male was passive while the female moved about the tank. Following this passive phase, which lasted 10–30 s, the male began rubbing his chin from side to side over the female's snout. The second phase occurred when the male arched forward, released his grasp, and moved ahead of the female. He then turned and moved directly back over the female until his body was even with the female's tail. At this point, phase 3, the male turned once again and resumed his clasp of the female and resumed rubbing his chin against the female's snout. The male became very excited during the third phase, his rubbing became more intense, and he began to rub his cloaca against the female's back by undulating his tail from side to side.

The capture stage led to the spermatophore initiation and deposition stages. In these two stages, the male released the female and moved ahead of her, his body vibrating intensely. With the female behind him, the male held his hind legs straight out to either side, pressed his cloaca against the substrate, and released a spermatophore. Males were observed releasing 1–3 spermatophores per courtship and no females were observed picking up the spermatophores. Males would stop depositing spermatophores if the female stopped following the male or if the male got too far out in front of the female.

Other characteristics arose in the courtship when two males or two females were placed in the breeding tank with one member of the opposite sex. When two males were placed with one female the non-courting male was observed to interrupt the courtship at all stages by amplexing with the pair or dislodging the courting male. When two females were placed with a single male, the non-courted female would align herself parallel to the courted female. As the male proceeded with the capture of the female he became disoriented and switched partners, amplexing with the non-courted female.

One female deposited eggs two days after courtship was observed. Egg laying began at 2230 h and continued until 0317 h. The female was observed climbing up onto twigs and other vegetation in the tank. Once finding a suitable location the female pressed her cloaca against the vegetation and deposited clumps of 1–13 eggs. A total of 212 eggs were laid in 4.75 h, most of them being deposited singly. None of the eggs was fertile.

I thank Melissa Ewert for help in collecting salamanders. I also thank Dr. James R. Coggins and Melissa Ewert for their critical comments on an early draft of the manuscript.

Submitted by **MATTHEW G. BOLEK**, Department of Biology, Carroll College, Waukesha, Wisconsin 53816, USA. Present Address: Department of Biological Sciences, University of Wisconsin–Milwaukee, Milwaukee, Wisconsin, 53201, USA; e-mail: bolek@csd.uwm.edu.

AMPHIUMA MEANS (Two-toed Amphiuma). **DIET**. On 19 August 1992, a recently drowned *Amphiuma means* (SVL 78.5 cm; TL 102 cm; mass with empty stomach 1350 g) was removed from a funnel trap in a cypress dome swamp in the Spring Creek Unit of Big Bend Wildlife Management Area, Taylor County, Florida, USA. While being preserved, the amphiuma regurgitated a crayfish and a *Regina rigida* (SVL 71.1 cm) that had been swallowed tail first. The snake was close to the record size (TL 79.7 cm) reported by Conant and Collins (1991. A Field Guide to Reptiles and Amphibians Eastern and Central North America. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.), but its total length could not be determined because the tail was partially digested. The only other recorded predators of *R. rigida* are *Rana catesbeiana* (Hensley 1962. Herpetologica 18:141) and *Lampropeltis getula* (Viosca 1926. Copeia 1926:109).

Submitted by **KEVIN M. ENGE**, Florida Game and Fresh Water Fish Commission, Route 7, Box 3055, Quincy, Florida 32351, USA.

AMPHIUMA TRIDACTYLUM (Three-toed Amphiuma). **ECTOPARASITES**. On 19 February 1995, an adult female *Amphiuma tridactylum* was captured in a small roadside ditch in Hammond, Tangipahoa Parish, Louisiana, USA. Three leeches were collected from the *Amphiuma*. These were identified as *Placobdella montifera* (1 specimen) and *P. multilineata* (2 specimens) by Ron W. Davies and were deposited in his reference collection at Monash University, Melbourne, Australia. The keeled-back leech (*P. montifera*) is known to parasitize a number of fish species (Bere 1931. Trans. Wisconsin Acad. Sci. Arts Letters 26:437–440; Meyer 1946. Trans. Amer. Micros. Soc. 65:237–249; Davies 1973. Can. J. Zool. 51:531–545; Amin 1981. Trans. Amer. Micros. Soc. 100:42–51) and has been collected from frogs, toads, mussels, and snails (Mathers 1948. Proc. Iowa Acad. Sci. 55:397–421). However, there are no reports of parasitic interactions between *P. montifera* and *Amphiuma*. In addition, *P. montifera* has not been previously encountered in Louisiana (Sawyer 1972. Illinois Biol. Monogr. 46. Univ. Illinois Press, Chicago. 155 pp.). This is also the first report of an amphibian parasitized by *P. multilineata*. This leech has been collected from turtles (Forrester and Sawyer 1974. J. Parasitol. 60:673; Sawyer and Shelley 1976. J. Nat. Hist. 10:65–97; Stone 1976. Southwest. Nat. 20:575–576), as well as on American alligators from Tangipahoa Parish, Louisiana, and Florida (Forrester and Sawyer, *op. cit.*; Cherry and Ager 1982. J. Parasitol. 68:509–510; Brantley and Platt 1991. Herpetol. Rev. 22:4–5).

SEAN DOODY**, Applied Ecology Research Group, University of Canberra, P.O. Box 1, Belconnen, ACT 2616, Australia.

EURYCEA JUNALUSKA (Junaluska Salamander). **MORPHOLOGY**. Thirty *Eurycea junaluska* larvae were collected from the Cheoah River (Graham Co., North Carolina, USA) on 12 May 1995. Two of these individuals (37.1 and 25.6 mm SVL) were observed to have scoliosis of the spinal column. This condition did not appear to hinder locomotion in the field nor in the lab and was confirmed by radiography. Because of incomplete ossification of the larval skeleton, the radiographs are of poor quality, but they are sufficient to demonstrate the vertebral malformations. The specimens and a radiograph are deposited at the North Carolina State Museum (NCSM39536–37).

Spinal abnormalities have been reported in other salamanders (e.g., *Plethodon glutinosus*; Marvin 1995. Herpetol. Rev. 26:30), but I am unaware of a record of the condition in pre-metamorphic individuals. Based on the size distribution of larvae at Cheoah River (T. J. Ryan, unpubl.) and nearby Santeetlah Creek (Ryan 1998. J. Herpetol. 32: *in press*), the affected individuals are likely representatives of the 1993 and 1994 hatchling classes. The affected individuals are of a size representative of their cohorts, indicating that the condition has not negatively influenced growth. I have not observed this condition in any other *E. junaluska* larvae, despite examining more than 100 *E. junaluska* larvae from the Cheoah River, and over 300 others from populations in western North Carolina (Ryan 1997. Copeia 1997:210–215) from April 1994 to present. That the affected individuals were from successive cohorts in the same population may suggest the condition is environmentally induced due to conditions unique to the Cheoah River site or possibly due to a heritable factor.

I thank Amy Patterson for providing the radiographs. Support was provided by Challenge Cost-Share Agreement between the Highlands Biological Station and the USDA Forest Service, National Forests in North Carolina, and Financial Assistance Award Number DE-FC09-96SR18546 from the U.S. Department of Energy to the University of Georgia Research Foundation.

PLETHODON IDAHOENSIS (Coeur d'Alene Salamander). **EGG MASS.** Although egg masses have been described for most western *Plethodon* no such description exists for *Plethodon idahoensis*. This salamander's secretive habits have prevented observation of its eggs in the wild (Lynch 1984. MS Thesis, Univ. Idaho, Moscow. 59 pp.). Herein we describe a clutch of eggs from a captive *P. idahoensis* obtained from the Kootenai River Valley, Lincoln County, Montana, USA during 1988. The eggs were discovered in an aquarium maintained in the Washington State University Department of Zoology and were laid during the week of 2–9 June 1989. Whether a female was in attendance is unknown. The egg mass (maximum dimension 21 mm) contained seven coherent, creamcolored eggs (mean = 5 mm; range 4.9–5.1 mm; SD = 0.07), each surrounded by two jelly capsules. There was no suspensory stalk; six of the eggs forming a single layer attached to paper toweling that lined the aquarium. This egg mass is similar to that described for the closely related *P. vandykei* (Jones 1989. Herpetol. Rev. 20:48). This egg mass has been deposited at the California Academy of Sciences (CAS 202842).

WILSON, JR.**, Department of Life Sciences, Spokane Falls Community College, MS 3180, 3410 Fort Wright Drive, Spokane, Washington 99204, USA, and **JOHN H. LARSEN, JR.**, Department of Zoology, Washington State University, Pullman, Washington 99164, USA.

PSEUDOEURYCEA GALEANAE (Galeana False Brook Salamander). **HABITAT USE**. Salamanders of the genus *Pseudoeurycea* are generally found in forested areas under rocks, rotten wood, in caves, or less commonly inside epiphytic bromeliads (Wake and Lynch 1976. Nat. Hist. Mus., Los Angeles Co. Sci. Bull. 25:1-65). *Pseudoeurycea galeanae* is endemic to Nuevo León, México, and is reported from four localities (Johnson et al. 1982. Herpetol. Rev. 13:51; Taylor 1941. Proc. Biol. Soc. Washington 54:81).

We conducted a diurnal search on 23 May 1997 at Puerto de Cieneguillas, 6 km S Pablillo, Nuevo León, México (24°31'10"N, 99°58'58"W, ca. 2577 m elev.) where *P. galeanae* was previously located (E. Liner, unpubl. data). The general habitat was a mixed forest of *Pinus* sp. and *Quercus* sp. We found three adult specimens (GP 45–47) inside dead *Agave* sp. The salamanders were located at the insertion of the leaves with the rotten trunk, up to 40 cm above the ground. The leaves were very wet, and small amounts of water with rotten plant matter had accumulated at the juncture of the leaves and trunk. After 45 min of searching not a single specimen was found under rocks or logs. The salamanders were found in the ecotone between the forest and small pastures. At the time of our visit the first rains of the season had began, but the amount of rain was small and the soil was still dry under rocks and logs. It seems likely that the salamanders use the leaves of the *Agave* (especially the rotten ones) as a refuge for aestivation

and temporary microhabitat when the soil is still dry, in the same way that more tropical species (e.g., *P. scandens*, *P. nigromaculata*) use bromeliads. This is an unusual microhabitat for non-tropical bolitoglossine salamanders. The use of plants above ground as habitat is common among tropical species inhabiting humid zones, but is not reported in temperate, more xeric areas. *Pseudoeurycea galeanae* is apparently uncommon, but the paucity of records may be due to the use of a habitat not usually surveyed for bolitoglossine salamanders.

We thank F. F. Pedroche for assistance in the field, and C. Bell and D. B. Wake for comments and suggestions. The collecting permit was provided by SEMARNAP, México. Funding was provided by a summer research grant from the Center for Latin American Studies to GPO and NSF BSR 90 19810. GPO is supported by a fellowship from CONACyT.

TARICHA GRANULOSA (Roughskin Newt). **BEHAVIOR.** On 6 May 1997 near Lake Cowichan, Vancouver Island, British Columbia, we observed a male *Taricha granulosa* in amplexus with a female *Ensatina eschscholtzii*. The pair was swimming in a small, temporal pool (ca. 2 m diameter and 50 cm deep), and the *T. granulosa* had the *E. eschscholtzii* firmly clasped in axillary amplexus. The salamanders separated when we picked them up for closer inspection. The *E. eschscholtzii* was extremely sluggish, suggesting that the amplexus had lasted for some time. The newt was in the smooth-skinned, breeding phase. The observation occurred between 1400-1500 h ca. 10 m from the shore of Lake Cowichan under the shaded canopy of Douglas fir *(Pseudotsuga menziesii)* and red cedar *(Tsuga heterophylla)*. Rain had fallen for several days, and conditions were favorable for salamander activity. The newt could have captured the terrestrial *E. eschscholtzii* along the edge of the pool and dragged it into the water. Alternatively, the *E. eschscholtzii* could have either fallen or ventured into the pool where the newt clasped it. On Vancouver Island, Guppy (1953. Victoria Nat. 10:25–27) found an *E. eschscholtzii* on the bottom of a small lake and suggested that *E. eschscholtzii* may occasionally venture into the water to rehydrate. Reports of indiscriminate clasping behavior involving salamanders are rare. To our knowledge, this is the first report of an interspecific amplexus between aquatic- and terrestrially-breeding salamanders.

ANURA

BUFO FERGUSONII (Ferguson's Toad). **ECOLOGY.** *Bufo fergusonii* Boulenger 1892, is a small (adult females to 46 mm SVL), terrestrial bufonid endemic to peninsular India. It also has been reported from Sri Lanka (Dutta. 1997. Amphibians of India and Sri Lanka [Checklist and Bibliography]. Odyssey Publ. House, Bhubaneswar. xiii + 342 + xxii pp.). Little is known of its ecology (Daniel 1963. J. Bombay Nat. Hist. Soc. 60:415–438; Rao 1915. Rec. Indian Mus. 11:31–38; Satyamurti 1967. Bull. Madras Govt. Mus. n.s. Nat. Hist. 7[2]:1–90). A series of eight breeding adults collected from the base of Pataravakkam Hill near Tiruvadisoolam (12°45'N, 80°04'E), Chengleput District, Tamil Nadu State, southeastern India, provided information on size, microhabitat, diet, and reproduction. Collections were made on 16 Nov 1997 between 1830–2040 h, after heavy showers that characterize the Northeast Monsoons in southeastern India. There were intermittent light showers during the period of collection.

Five gravid females measured 34.2–44.3 mm SVL (mean 40.84 ± 1.87 SE) and weighed 3.3–10.1 g (mean 7.04 ± 1.25 SE); three adult males measured 30.4–33.7 mm SVL (mean 31.53 ± 1.19 SE) and weighed 2.2–3.5 g (mean 2.9 ± 0.38 SE). All males had pale yellowish median subgular vocal sacs, but no nuptial pads. These specimens were taken from an undulating area dominated by scrub forest. All females and two males were found in wet grassy clearings among scrub and grassy puddles; one male was found floating on the surface of a ca. 0.3 m deep ephemeral pool with dense shore vegetation.

All toads contained food in their stomachs. Of the 20 prey items discovered, 17 (85%) were Formicidae, 2 (10%) Coleoptera, and 1 (5%) Hemiptera. Number of items in stomach samples ranged from 1–5 (mean 3.5; N = 8), and although females showed more prey items (1–5) than males (1–2), this difference was not statistically significant (paired *t*-test, $P < 0.05$). Prey length varied between 3.3–11.2 mm (mean 7.32 ± 1.37 SE; N = 5). Rao (*op. cit.*) mentioned that *B. fergusonii* is a termite specialist, avoiding ants, beetles, and earthworms.

All males had enlarged testes, and all females carried unpigmented eggs (0.08–0.1 mm diam). Clutch weight and relative clutch mass in five females ranged from 0.4–2.5 g (mean 1.50 ± 0.40 SE) and 0.08–0.27 (mean 0.21 ± 0.04 SE).

We thank Tharaq Andrews, Romaine Andrews and Kathryn Hawkswell for assistance in collection and Romaine Andrews for transport.

DENDROBATES AURATUS (Black-and-Green Poison Dart Frog). **PREDATION.** At ca. 0930 h on 26 March 1995, an adult rufous motmot (*Baryphthengus marhi*) was observed in secondary lowland tropical forest located at Estacion Biologica La Suerte, near the town of Cariari in the Province of Limon, northeastern Costa Rica. The bird was ca. 25 m from a hiking trail and was perched on a bare branch in an exposed position ca. 3 m above ground. The lone individual was observed with binoculars for ca. 4 min. Another bird landed on the same branch and sat next to the original individual. The newly arrived motmot was grasping a *Dendrobates auratus* in its beak which it immediately fed to the original individual. In the field is difficult to distinguish male and female rufous motmots, however this behavior was interpreted as a male feeding the female as a courtship gesture. Both individuals had the diagnostic black mask on the breast and racquet-tails indicative of adult birds. The pair continued sitting on the branch for ca. 30 min., after which they flew off together into the forest. Neither individual appeared to suffer any ill effects from either grasping or consuming the *D. auratus* during this period.

Although this foraging behavior has not been documented in

the field, blue-crowned motmots (*Momotus momota*) inhabiting the rainforest exhibit at the National Aquarium in Baltimore have consumed *D. auratus* and several other species of poison dart frogs (C. Rowsom, pers. comm.).

I thank Tom LaDuke of East Stroudsburg University and Brent Graves of Northern Michigan University for their encouragement and assistance with this note.

PHYSALAEMUS CENTRALIS (NCN). **MALE-MALE COMBAT.** The genus *Physalaemus* contains 37 species and is distributed throughout the Mexican lowlands to northern Argentina (Frost 1985. Amphibian Species of the World. Allen Press, Lawrence, Kansas, 732 pp.). The occurrence of male-male combat within the genus is only reported for *Physalaemus pustulosus* (Ryan 1985. The Túngara Frog: A Study in Sexual Selection and Communication. University of Chicago Press, Chicago, Illinois. 230 pp.) and *P. cuvieri* (Barreto and Andrade 1995. Amphibia-Reptilia 16:67–76).

Herein I report field observations of eight male-male combats in *Physalaemus centralis*, observed 20–21 November 1996 in temporary ponds at the Centro de Pesquisas e Treinamento em Aquicultura, near Cachoeira das Emas, municipality of Pirassununga (47°25'28"W; 21°59'52", 620 m), state of São Paulo, southeastern Brazil.

Males often called while floating in small puddles (ca. 5 cm diameter and 3 cm deep). In a typical encounter, the invader frog quietly and slowly approached the calling resident from behind. When the distance between the two males was less than 10 cm, the invader rapidly approached the resident, jumped underneath it, and using kicks, moved it out of the calling site. The resident would then quickly return to the site and jump on the invader, holding it in a venter-venter position. The two frogs rolled on the ground or in the water until separating. In all combat bouts observed, the winner was always the resident male. In eight observations, the loser returned five times to the original calling site and repeated the fight sequence two or three times. The combat bout terminated when the loser dispersed and the winner resumed calling. Combat bouts lasted from one to three minutes. No calls were heard during the interactions.

I thank CEPTA-IBAMA for logistical support and CAPES for financial support. Ivan Sazima and Ariovaldo Giaretta read the manuscript and provided helpful suggestions. Ellen Wang read the English version.

RANA AURORA DRAYTONII (California Red-legged Frog). **EGG PREDATION.** The designation of the California red-legged frog (*Rana aurora draytonii*) as Threatened by the U.S. Fish and Wildlife Service (Fed. Reg. 23 May 1996, 61[101]:25813–25833) has heightened concern about mortality from predation. Of special concern has been the potential impacts of the introduced bullfrog (*R. catesbeiana*) and exotic fishes on tadpoles and adults (reviewed in Fed. Reg. 2 Feb 1994, 59[22]:4888–4895). Virtually no information, however, has been published on predation of eggs in *R. a. draytonii*.

On 12 March 1997, at Lower Staub Pond (Swanton-Pacific Ranch, Scott Creek drainage, Santa Cruz County, California, USA), I found a 1 to 2-day-old red-legged frog egg mass. It was located at the surface of the water and was attached to the outer stems of a clump of *Juncus*. The water depth was about 25 cm.

I watched several newts (*Taricha* sp.) feeding on the eggs from 1620–1715 h. There were always 1–3 newts at the egg mass, and I estimated 6–8 individuals ate up to four eggs each during my observations.

During ingestion, each newt faced the egg mass and snapped up a single jelly-encased ovum with a short lunge. While the egg was grasped in the mouth, each newt shook its head violently back and forth 4–5 times in 2–4 bouts separated by about 2–3 s. The egg was dislodged from the mass by this shaking, and perhaps the jelly envelope was also removed. Swallowing motions followed the shaking. The forelegs were not used during ingestion.

After observing the feeding newts, I captured a female that had ingested two eggs, which were regurgitated in my hand. The eggs appeared to be without jelly envelopes. I dissected the newt, but found her digestive tract empty. On the afternoon of 11 March 1997, 5 Gee minnow traps (ca. 43 cm long, 2 cm diameter entrance, 6 mm mesh) were set about 2 m from shore along the perimeter of Lower Staub Pond. When the traps were checked mid-morning the next day, they yielded 46, 34, 30, 22, and 3 newts. These numbers corroborated my observations that the population of *Taricha* in the pond was large.

Egg and tadpole predation by native newts may be an important factor in *R. a. draytonii* population dynamics that should be considered along with other documented forms of predation.

I am grateful to Walter R. Mark, California Polytechnic State University, San Luis Obispo, for permission to work on the Swanton-Pacific Ranch. Assistance from Jae Able, Susan Christopher, Mark Jennings, Dawn Smith Reis, and Norm Scott, Jr., was also appreciated.

XENOPUS LAEVIS (African Clawed Frog). **PREDATION.** Avian predation on *Xenopus laevis* has been documented in Africa but not in extralimital populations in the United States. Here we offer evidence of predation by birds in a recently discovered population of *X. laevis* in southern California.

On 21 May 1996, while examining black-crowned night heron (*Nycticorax nycticorax*) nests at Piute Ponds on Edwards Air Force Base, southwest of Rosamond Lake, Los Angeles Co., California (34°47'N, 118°7'W), RLH found a ca. 21-day old chick that regurgitated the partial carcass of *X. laevis*. The carcass was retained and the partial skeleton was deposited at the University of California, Davis (UCDMZ 12275). During a subsequent visit on 17 October 1996, JJC observed >10,000 adult and recently metamorphosed *X. laevis*. Eight recent metamorphs were collected and catalogued into the California Academy of Sciences (CAS 202468–475) .

To further document predation of *X. laevis,* JJC collected bird pellets from beneath a Fremont cottonwood (*Populus fremontii*) at the north edge of one of the ponds where the frogs were observed. This tree was the site of an active great blue heron (*Ardea herodias*) nest during May 1996. Based on skeletal characteris-

tics, 12 of 25 pellets contained the remains of *X. laevis* and 13 contained the remains of rodents or birds. Among those pellets containing frog remains, 10 contained skeletal elements from a single frog and two contained parts of two frogs.

In a Joshua tree (*Yucca brevifolia*) ca. 0.5 km from the first nest and 30 m south of the water's edge, was another great blue heron nest, which had also been active during May 1996. An examination of 16 pellets found under this nest yielded no frog bones. However, bones from a single *X. laevis* were found on the ground amid other bird and mammal bones and weathered pieces of pellets.

During a third trip on 21 December 1996, JJC examined ca. 250 pellets found under seven Joshua trees and two willow trees (*Salix* sp.) on the pond's perimeter. These contained the remains of 22 *X. laevis,* 12 of them singly in pellets and 10 of them in pellets containing two frogs. One pellet contained bird bone fragments mixed with *X. laevis* bones and another contained kangaroo rat (*Dipodomys* sp.) bones mixed with bones of two *X. laevis.*

Piute Ponds consist of ca. 80 h of flooded desert playa, with perennial open water and extensive cattail (*Typha angustifolia*) and bulrush (*Scirpus* spp.) marshes. Several species of wading birds, including great egrets (*Ardea alba*), great blue herons, black-crowned night herons, and snowy egrets (*Egretta thula*) are present year round. Ciconiiformes with similar feeding capabilities, including black-headed herons (*Ardea melanocephala*) [O'Connor 1984. Ostrich 55:221–222], yellow-billed egrets (*Egretta intermedia*) [Bates et al. 1992 Ostrich 63:44], hamerkops (*Scopus umbretta*) [Loveridge 1953. Bull. Mus. Comp. Zool. Harvard 110:325–406], and Marabou storks (*Leptoptilus crumeniferus*) [Kahl 1966. J. Zool. 148:289–311] are documented predators of *Xenopus* spp. in Africa. Thus, any Ciconiiformes at Piute Ponds are potential predators of *X. laevis.* However, without direct observation we cannot be certain which species other than black-crowned night herons produced the pellets containing the *X. laevis* bones.

We thank W. Deal and M. Hagen for permitting access to the site and M. Jennings and T. Custer for their review of this note. Specimens were collected under California Department of Fish and Game Scientific Collecting Permit #803046-03.

Submitted by **JOHN J. CRAYON** and **ROGER L. HOTHEM**, U.S. Geological Survey, Biological Resources Division, California Science Center, Davis Field Station c/o Wildlife, Fish, and Conservation Biology, University of California, Davis, California 95616-5224, USA.

GYMNOPHIONA

SIPHONOPS HARDYI (Hardy's Caecilian). **PREDATION.** On 11 September 1994 after a rainy night we collected a juvenile Maximilian's snake-necked turtle (*Hydromedusa maximiliani*; 105 mm straight-line carapace; 91 g) biting an "earthworm-like" prey at midbody. The turtle was discovered in a dammed portion of a hillside streamlet covered by coastal rain forest (Atlantic Forest) at the Sítio Três Marias, Municipality of Marechal Floriano, State of Espírito Santo, eastern Brazil (20°24'36"S, 40°49'26"W), ca. 680 m elevation. The prey was the small, subterranean, and poorly known caecilian *Siphonops hardyi* (163 mm TL, 4.5 g). This appears to be the first record of a turtle preying on a caecilian. It is possible that such predatory events are uncommon due to habitat segregation of the aquatic predator and its subterranean prey. The turtle and its prey are in the Coleção Zoológica da Universidade Federal do Espírito Santo (ZUFES 150391 and 140348).

We thank I. Sazima, P. R. Manzani, and M. Wilkinson for reading the manuscript, M. Wilkinson and P. R. Manzani for identification of the caecilian and the turtle, and PICDT/CAPES for a grant to CZ.

Submitted by **CLAUDIO ZAMPROGNO** and **MARIA DAS GRAÇAS F. ZAMPROGNO**, Departamento de Biologia, Universidade Federal do Espírito Santo, 29040-090 Vitória, Espírito Santo, Brazil. e-mail (CZ) czamprog @ server.npd.ufes.br.

CROCODYLIA

ALLIGATOR MISSISSIPPIENSIS (American Alligator) and ***GOPHERUS POLYPHEMUS*** (Gopher Tortoise). **COMMENSALISM.** During a gopher tortoise relocation project in Collier County, Florida, USA, an excavated tortoise burrow revealed a 76.2 cm *Alligator mississippiensis* sharing the burrow with an adult tortoise. The burrows being excavated were located in a saw palmetto (*Serenoa repens*) prairie, which exhibits higher elevations and drier conditions than most wooded habitats in Florida. The burrows were excavated during the first part of May 1996. This is the beginning of the rainy season in Florida, and most lakes and canals have very low water levels at this time. The nearest standing water, a 4.6 ha pond cypress (*Taxodium ascendens*) swamp, is ca. 430 m from the tortoise burrow.

Some of the more common and documented commensals known to utilize *G. polyphemus* burrows in southwest Florida include *Rana areolata* (Gopher Frog), *Drymarchon corais couperi* (Eastern Indigo Snake), and *Crotalus adamanteus* (Eastern Diamondback Rattlesnake). To my knowledge, this is the first observation of an *Alligator mississippiensis* sharing a burrow with *G. polyphemus.*

Submitted by **STEPHANIE M. VORIS**, Wilson, Miller, Barton & Peek, Inc., 3200 Bailey Lane, Suite 200, Naples, Florida 34105-8507, USA.

TESTUDINES

LEPIDOCHELYS KEMPI (Kemp's Ridley Sea Turtle). **DIET.** Adult *Lepidochelys kempi* diets have been well documented in the Gulf of Mexico (Marquez 1990. Food and Agriculture Organization Fisheries Synopsis: Sea Turtles of the World. No. 125, Vol. 11. Rome, FAO. 81 pp.). However, little is known about this turtle's feeding habits as a subadult or its feeding habits along Georgia's coast. Here, we report the stomach/gastrointestinal tract contents of 12 stranded, juvenile to adult-sized *Lepidochelys kempi* (Table 1). These collections were obtained from 1992 to 1997 from Wassaw Island, Georgia, USA (31°55'0"N, 80°56'0"W).

All stomach and gastrointestinal tract contents examined from *L. kempi* are considered to be relatively shallow water inhabitants ($\leq$ 25 m deep) (Ruppert and Fox. 1985. Shallow Water Marine Benthic Macroinvertebrates of South Carolina. University of South Carolina Press, Columbia. 330 pp.). This further supports the belief that *L. kempi* commonly inhabit and feed in shallow water environments.

We thank Robert A. Moulis, Kristina L. Williams, and Randy Isbister for their guidance and support on Wassaw NWR, and the Georgia Department of Natural Resources (Brad Winn, John Jensen, Mike Harris, and Steve Pete) and U.S. Fish and Wildlife Service (John Robinette, Sam Drake, Mark Musaus, Charles Warnock, and Jim Stockie) for supporting such investigations along the Georgia coast.

TABLE 1. Stomach/gastrointestinal tract contents of *Lepidochelys kempi* from Wassaw Island, Georgia, USA.

LACERTILIA

CTENOSAURA SIMILIS (Ctenosaur, Garrobo, Iguana Negra). **BEHAVIOR.** Recently I observed a predation event involving a frog distress call that attracted a large ctenosaur, presumably by the opportunity to pirate a meal, allowing the frog to escape from its original predator (a colubrid snake). Although anecdotal, this observation is one of only a few examples in the herpetological literature of predator attraction to distress calls, and the second example of a selfish benefit to distress calling in an amphibian.

The Río Cabuyo, in the Lomas Barbudal Biological Reserve in Guanacaste, Costa Rica (10°30'N, 85°23' W), is a small river with a stable flow of ground water during the long dry season (December–May). The river bank has a narrow flood plain about 1–3 m wide leading from the water's edge to a steep embankment created by erosion during times of high water in the wet season. On the afternoon of 30 March 1993, a racer (*Coluber* [= *Masticophis*] *mentovarius*), about 1.5 m in total length, captured a large frog (species unknown) on the narrow flood plain near the water's edge. The frog, emitting a series of loud yelping sounds, was held firmly in the mouth of the snake with its forelimbs and head extending from the snake's mouth. Within about 5–10 s, a large ctenosaur (*Ctenosaura similis*), situated about 10 m beyond the embankment, advanced through the dry leaf litter on the forest floor to the cusp of the steep embankment, then quickly dropped the 2 m to the flood plain, and ran directly toward the frog and snake. Before the ctenosaur reached the frog and snake, the frog broke free from the snake's grasp. In two long leaps the frog jumped into the stream and was carried by the current to safety. It was not clear whether the snake voluntarily released the frog, or if the frog took advantage of the distraction caused by the abrupt appearance of the ctenosaur to struggle free. For about 5 min after the frog had escaped, the snake and ctenosaur searched the flood plain in the area where the frog had been captured, all the while maintaining a distance of at least 1–2 m from each other.

The topography of the embankment prevented the frog/snake interaction from being visible from the forest floor where the ctenosaur initiated its approach. The acoustic distress signal however, would have been clearly audible to the ctenosaur. This anecdote further supports the hypothesis that distress calls benefit the signal sender by attracting secondary predators that interfere with the primary predator, thereby creating an opportunity for escape.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard). **PREDATION.** In extreme northern Chihuahua, México, near its border with New Mexico, few thorn-bearing bushes are available in the dune habitat for use by verdugos (loggerhead shrikes, *Lanius ludovicianus*), which substitute barbed wire fences both as perches and as impaling devices on which prey are temporarily stored. Prey, ranging in size from grasshoppers to rufous-sided towhees, are known to have been impaled on barbed wire (Vander Wall 1990. Food Hoarding in Animals. University of Chicago Press, Chicago, Illinois). Although it is not surprising that verdugos prey upon *Phrynosoma cornutum*, we are unaware of reports of these lizards being impaled. Therefore, we offer the photograph in Fig. 1 (UCM 58818, 49 mm SVL), taken during a lizard survey on Rancho El Tule, Chihuahua, near the Mexico-New Mexico border (31°45'N, 107°13'W), 4 June 1997. A pair of *L. ludovicianus* was seen on this fence in the immediate vicinity of the impaled *P. cornutum*.

FIG. 1. *Phrynosoma cornutum* impaled on barbed wire by a verdugo (*Lanius ludovicianus*).

LEMOS ESPINAL**, Laboratorio de Conservacíon, CyMA, UIICSE, Escuela Nacional de Estudio Profesionales Iztacala, UNAM, Apartado Postal 314, Tlalnepantla, México, México, **DAVID CHISZAR,** Psychology, CB 345, University of Colorado, Boulder, Colorado 80309-0345, USA, **CLINT HENKE**, 11823 Eaton Way, Westminster, Colorado 80020, USA, and **HOBART M. SMITH,** EPO Biology, CB 334, University of Colorado, Boulder, Colorado 80309-0334, USA.

PHRYNOSOMA DOUGLASI (Short-horned Lizard). **REPRODUCTION.** *Phrynosoma douglasi* (= *P. hernandezi*; Zamudio et al. 1997. Syst. Biol. 46:284–305) is widespread in Wyoming, yet nothing is known about its reproductive biology in the state (Baxter and Stone. 1980. Amphibians and Reptiles in Wyoming. Wyoming Game and Fish Department). Here we report the date of parturition for a female *P. douglasi*, as well as offspring characteristics.

We collected a gravid female (70.0 mm SVL, 27.0 mm TL, 29.0 g mass) on 26 July 1997 near Flaming Gorge National Recreation Area, Sweetwater County, Wyoming, USA. She was brought back to a lab at the University of Colorado, Boulder, where she gave birth 6 August 1997 to 13 offspring (4 of which were stillborn). After birth, the female weighed 13.3 g and the total offspring mass was 11.2 g. Thus, the relative clutch mass (offspring mass/female mass) = 0.84. The sex ratio of the offspring was 9 males: 4 females (5 males: 4 females for the live offspring; all 4 stillborns were males); mean offspring mass = 0.86 g (mean

mass live offspring = 0.85; mean mass stillborn offspring = 0.87 g); mean offspring SVL = 23.8 mm (mean SVL live offspring = 24.1 mm; mean SVL stillborns = 23.3 mm). The female and her offspring were released 10 August 1997 at their capture site.

This clutch consisted of offspring of two different colors, pink and gray. Three out of four live females were gray, whereas four out of five live males were pink (stillborns could not be classified as either color, although they looked more pinkish). The function of this coloration, and whether the coloration differences are retained throughout life, are not known at this time. However, it is of interest that *Crotalus viridis concolor*, and possibly *Sceloporus undulatus elongatus*, at this same locality also show two color morphs (tan versus pink, and gray versus pink, respectively; pers. obs.). Thus, there may be an ecological factor that makes it advantageous for reptiles in this area to produce young of different colors.

UNDERWOODISAURUS MILII (Thick-tailed Gecko). **CROSS PREDATION**. Observations of invertebrates feeding on vertebrates under natural conditions are rare. How et al. (1990. Rec. West. Aust. Mus. 14[4]:449–459) report centipedes to be a relatively common prey item for *U. milii* from Western Australia. We witnessed a scolopendromorph centipede (*Cormocephalus aurantiipes*, 94 mm) killing and partially consuming a subadult gecko (*Underwoodisaurus milii*, 80 mm SVL) on a granite outcrop in Victoria, Australia. Our observation suggests cross predation between centipedes and *U. milii*; that is, *U. milii* may alternately be prey or predator of centipedes (see also Bauer 1990. Herpetol. Rev. 21: 83–87; McCormick and Polis 1982. Biol. Rev. 57:29–58).

On 24 April 1997 at 1250 h we lifted a rock, disturbing a large *C. aurantiipes* (approx. 90 mm) attacking a subadult *U. milii*. The centipede's head was positioned, ventral side uppermost, underneath and to the left of the lower jaw of the gecko, which was held firmly by the centipede's telopodites (venom claws). The centipede's body passed under the gecko's head and down the right flank, its legs tightly gripping the gecko's body. The gecko's tail was not restrained, nor had it been autotomized. The centipede repeatedly stabbed the gecko's throat with its venom claws, drawing blood. We suspect that the gecko was injected with venom and paralyzed at this time (see Mendez et al. 1990. J. Morph. 206:303–312). The centipede used its mandibles and maxillae in tandem with the venom claws, and its antennae were active throughout.

The gecko struggled occasionally but appeared dead by 1300 h, at which time the centipede released its tight grip, then flipped the gecko to expose its ventral surface. While using the distal end of its body to pin the gecko securely to the substrate, the centipede opened the flesh of the gecko's throat with its venom claws and chewed with its mandibles and maxillae. The centipede released its prey at 1315 h, at which time we collected the gecko. It measured 41 mm SVL and 25 mm TL. We examined its wounds (the centipede had removed the flesh surrounding the lower jaw of the gecko) before replacing the gecko under the rock near the centipede. At 1415 h the centipede resumed feeding, this time on the hind leg. We continued our observations for an additional 15 min, during which time the centipede consumed all the flesh from the cloacal region of its prey. Observations ceased at 1430 h, at which time the centipede was consuming the area of the abdominal cavity. We returned on 13 May, to find the skeletal remains of the gecko under the same rock, but the centipede was no longer present.

It is likely that we initiated this predation event. An adjacent rock we had lifted previously had harbored a large *C. aurantiipes* that was no longer present upon subsequent inspection, and it may have moved under the rock with the *U. milii*. However, the efficiency with which the centipede dispatched and consumed the gecko, the abundance of both species in the study area, and the similarity of the shelter sites (exfoliated rock) suggest that this is not an unusual event.

SERPENTES

BOTHROPS AMMODYTOIDES (Yarará ñata, Patagonian Lancehead). **PREY**. *Bothrops ammodytoides* is a medium-sized (450–750 mm total length) lancehead that is endemic to Argentina. Available data indicate that *B. ammodytoides* feeds on lizards (Serie 1919. Physis 4:538–539) and rodents (Miranda et al. 1983. Guía de los Ofidios Bonaerenses. Asoc. Coop. Jard. Zool., La Plata. 71 pp.). An adult female *B. ammodytoides* (SVL ca. 550 mm, 300 g) was found at 1230 h on 11 January 1996 on a mountain trail, near a creek, in Río Seco Canyon, 5 km NW of Villa Larca, San Luis Province, Argentina. The snake was eating an adult *Odontophrynus occidentalis* (estimated mass = 20 g). When we captured the snake, it regurgitated the frog. The frog was deposited in the herpetological collection of the Departamento de Ciencias Naturales, Universidad Nacional de Rio Cuarto (ZV-UNRC 3784), and the snake is being kept alive in the Instituto de Herpetologia, Fundacion Miguel Lillo, Tucumán. Although other *Bothrops* species include amphibians in their diets, this type of prey has not previously been recorded for *B. ammodytoides*.

BUNGARUS MULTICINCTUS (Many-banded Krait). **DIET**. While the ophiophagous habits of kraits (*Bungarus* spp.) generally are well recognized, several other prey types, especially fish, are commonly taken by some species (Mao 1970. Herpetologica 26:45–48). However, lizards apparently are rare in the diets of kraits in the wild, with only four cases of lizard prey in the 112 specimens of nine species of *Bungarus* for which data are available (Slowinski 1994. Herpetol. Rev. 25:51–53). Here I report on another case of lizard prey in wild *Bungarus*. A subadult *Bungarus multicinctus multicinctus* (total length ca. 52 cm) that had been chopped to pieces in Yangon, Myanmar (= Rangoon, Burma) was found to contain an unidentified, partly digested skink (total length > 11 cm). Prey mass was at least 22% of predator mass. Both specimens are deposited in the collection of the Senckenberg Museum (SMF 73341).

Submitted by **ULRICH KUCH**, Sektion Herpetologie, Forschungsinstitut Senckenberg, Senckenberganlage 25, D-60325 Frankfurt, Germany.

CONOPSIS NASUS (Largenose Earth Snake) **REPRODUCTION.** Insofar as known, *Conopsis* and the closely related *Toluca* are live- bearing. Greer (1966. Copeia 1966:371–373) found 22 gravid females in a series of 104 *C. nasus* collected at Alvarez, San Luis Potosí, México during October and November. The number of embryos in these females varied from one to six and the degree of development of the embryos varied from barely recognizable to almost full term. A female *C. nasus* (38 cm total length) collected in the city of Queretaro, México on 4 April 1997 aborted two embryos after an injury on 5 June and gave birth to four live and one dead snake on 19 June 1997. The young snakes were approximately 10 cm total length. One of us (SAM) has collected *Conopsis* of this size in Queretaro and Guanajuato during late July.

CORALLUS CROPANII (NCN). **HABITAT and DIET.** *Corallus cropanii* is known from a restricted area of the Atlantic Forest in southeastern Brazil (Henderson and Puorto 1993. Cat. Amer. Amphib. Rept. 575:1–2), and nothing is published on its biology (Henderson et al. 1995. Herpetol. Nat. Hist. 3:15–27). Here we report substrate use and gut contents of the holotype, housed in the collection of the Instituto Butantan in São Paulo (IB 15200). The snake was collected in 1953, about 1.5 m above ground in a tree (J. Santos, pers. comm. to JC in 1953). After collection it was maintained in captivity for one week. An arboreal tendency was obvious; the snake spent most of the week above the ground. In 1997 we dissected this specimen and in the hindgut we found hair of the brown four-eyed opussum, *Metachirus nudicaudatus* (Marmosidae). An arboreal habit and mammalian prey are recorded for *Corallus caninus* (Henderson 1993. Herpetol. Nat. Hist. 1:91–96), which is considered a sister species of *C. cropanii* (Kluge 1991. Misc. Publ. Mus. Zool. Michigan 178:1–58).

We thank I. Sazima for suggestions on the manuscript and K. G. Facure for the identification of the mammal prey.

CROTALUS VIRIDIS CONCOLOR (Midget Faded Rattlesnake). **DRINKING FROM SKIN.** Some agamid lizards and snakes have been observed drinking from their skin (Greene. 1997. Snakes: The Evolution of Mystery in Nature. University of California Press, Berkeley. 351 pp.; Schwenk and Greene. 1987. J. Herpetol. 21:134–139). Here we report a similar behavior in *Crotalus viridis concolor* in the Flaming Gorge National Recreation Area, Sweetwater Co., Wyoming, USA. On 18 July 1997 at ca. 1600 h we located an adult male *C. v. concolor* (56.0 cm SVL) that had a radiotransmitter implant. As it began to rain the snake emerged from its burrow and drank water that had gathered in a depression of a small (4 x 10 cm) rock. Then, the snake moved back to the burrow entrance and loosely coiled, with part of its coils exposed to rainfall. After rain drops had accumulated on the exposed portion of its body, the snake began drinking from its skin. It continued drinking intermittently for ten minutes.

We thank Alan de Queiroz for comments on the manuscript.

GRAYIA CAESAR (African Banded Water Snake). **SEXUAL DIMORPHISM.** The rare and poorly-studied aquatic colubrid *Xenurophis caesar* Günther, 1863 was described on the basis of an adult female (BMNH 1946.1.6.38). *Grayia tholloni* Mocquard, 1897 seemed to bridge so well the gap between *X. caesar* on the one hand and *Grayia smithii* and *G. ornata* on the other hand that Mocquard (1897. Bull. Soc. Philom. Paris 8[9]:5–20) and later Boulenger (1901. Ann. Mus. Congo Belge. Zool. Sér. I Tome II, fasc. I:1–14) stated that these four species had to be placed in a single genus. While studying the relationships between these forms, we examined all 27 available specimens of *G. caesar* in the Muséum national d'Histoire naturelle (MNHN, Paris), Musée Royal de l'Afrique Centrale (MRAC, Tervuren), British Museum of Natural History (BMNH, London), and Institut Royal des Sciences naturelles de Belgique (IRSNB, Brussels): 16 females and 11 males whose sex was determined by tail dissection.

Four notable sexually dimorphic characters were revealed in *G. caesar:* anal scale state, number of white bands on body, number of ventral scales, and number of subcaudal scales. All males have an undivided anal, while all females but one (BMNH 1912.6.27.24) have a divided anal. This represents an original and new sexually dimorphic character among snakes. The males have fewer white bands on the body than females (males: mean ± SD = 24.0 ± 2.1, range = 21–28, N = 11; females: mean ± SD = 27.6 ± 1.5, range = 26–30, N = 16). This difference was statistically significant (Mann-Whitney U Test, $P \leq 0.05$). The bands are also present on the tail, which is rarely entire, as in many other aquatic snakes. Dowling's system (1951. Brit. J. Herpetol. 1:97–99) was used for counting ventrals. The number of ventrals ranges from 123 to 127 in males (125.0 ± 1.2, N = 11) and from 136 to 145 in females (139.8 ± 2.4, N = 16). Thus, ventral counts are non-overlapping (Mann-Whitney U, $P \leq 0.05$). The number of subcaudals in specimens with an entire tail ranges from 151 to 162 in males (157.5 ± 4.2, N = 6) and from 140 to 146 in females (143.3 ± 2.8, N = 4); thus, this character also separates the sexes ($P \leq 0.05$).

We thank C. McCarthy and B. Clarke (BMNH), and G. Lenglet (IRSNB) for reception in their museums, and A. Dubois, I. Ineich, and B. Hughes for constructive discussions. G. Josens provided working facilities at the Université Libre de Bruxelles.

PITUOPHIS MELANOLEUCUS DESERTICOLA (Great Basin Gopher Snake). **REGIONAL HETEROTHERMY.** On 3 July 1997 at 1230 h in the Flaming Gorge National Recreaation Area, Sweetwater Co., Wyoming, USA, I observed an adult female *P. m. deserticola* that was coiled loosely under the west side of a rock. The majority of its body was under the rock in the shade. However, a portion of its body (ca. 20–30 cm beginning ca. 50

cm from the head) was fully exposed to the sun. The snake had a noticeable bulge, indicating a prey item, in the region that was fully exposed to the sun. This female had been captured and measured (132 cm SVL; 573 g) on 22 June 1997. Neither then, nor when relocated on 25 June did the snake have a bulge in its body.

Regional heterothermy occurs when an organism maintains one region of its body at a different temperature than the rest of its body. This behavior has been observed in snakes that have recently eaten or are gravid (Greene 1997. Snakes: The Evolution of Mystery in Nature. University of California Press, Berkeley. 351 pp.). Regional heterothermy may increase digestive efficiency while reducing exposure to predators (Greene, *op. cit.*) and/or reducing metabolic rate. My observation is a possible example of regional heterothermy to aid digestion.

I thank Alan de Queiroz for comments and suggestions on this manuscript.

USA: CALIFORNIA: HUMBOLDT CO: Humboldt State University campus, Arcata [West 1/2 Sec. 28, T6N, R1E; (124°04'33"W, 40°52'38"N; UTM coordinates: 409350E, 4525470N, Datum: NAD27 CONUS; UTM Zone 10); average elevation of campus = ca. 60 m]. 6 May 1964. M. D. Be'aston. Humboldt State University Vertebrate Museum Collection (HSU 326, formerly A64-43). Verified by R. B. Bury. Extends northern coastal range ca. 54 km (33.3 mi) S from near Orick, Humboldt County (MVZ 44368–75, 56068, 81852–60) [Brodie 1970, Herpetologica 26:502; USDA Forest Service, Regional Ecosystem Office, Portland, Oregon, unpublished draft survey protocol with range map]; and ca. 1.6 km (ca. 1.0 mi) S and ca. 11.3 km (70 mi) W of the nearest southernmost coastal foothills record which is ca. "3.1 mi (ca 5.0 km) E of Blue Lake off Rt. 299" (MVZ 66531–34) (Brodie, *ibid.*; Norman and Schmidt, pers. observ.)].

Plethodon elongatus occurs farther south in inland Humboldt County (Jones and Raphael 1990, Herpetol. Rev. 21:37; Schmidt and Norman 1997, Herpetol. Rev. 28:206). However, no records exist as far south as the HSU 326 record on the northern California coast (Brodie, *ibid.*; L. Ollivier, pers. comm.; Schmidt and Norman, pers. observ.). The HSU collection catalog states that this "adult" (SVL = 45.2 mm, Norman, unpublished data) was "taken at night" (Norman, pers. observ.). No further specimens of *P. elongatus* have been documented from the area since the collection of HSU 326 and, because the campus has been heavily landscaped over the last three decades, the species may now be extirpated from the area (Ollivier and Norman, pers. observ., and Bury, pers. comm.).

No unpublished or published records filling the gap between the previous Orick records and HSU 326 exist in the Six Rivers National Forest database (Schmidt and Norman, pers. observ.). HSU 326 constitutes the first published record for the species south of the Mad River per se, the overall westernmost record for the county, and the southernmost coastal record for the species.

Submitted by **BRADFORD R. NORMAN**, 69 Midway Court, Arcata, California 95521, USA, and **GREGORY A. SCHMIDT**, Six Rivers National Forest, 1330 Bayshore Way, Eureka, California 95501, USA.

ANURA

ACRIS CREPITANS BLANCHARDI (Blanchard's Cricket Frog). USA: MINNESOTA: HENNEPIN CO: Bloomington, near the confluence of Nine Mile Creek and the Minnesota River (NW Sec. 28, T116N, R24W). 14 June 1998. Andrew Forbes, Delvin Jones, and John Moriarty. JFBM 13727. Verified by James Underhill. An additional 40–50 frogs heard calling. County record (Oldfield and Moriarty 1994, Amphibians and Reptiles Native to Minnesota. Univ. Minnesota Press, Minneapolis. 237 pp.). First report of this species from the state in the last 17 years.

Submitted by **JOHN J. MORIARTY**, Hennepin Parks, 3800 County Road 24, Maple Plain, Minnesota 55359, USA, **ANDREW FORBES**, 13416 Xerxes Avenue South, Burnsville, Minnesota 55337, USA, and **DELVIN JONES**, 4208 Kemrich Circle, Minnetonka, Minnesota 55345, USA.

ATELOPUS CRUCIGER. VENEZUELA ESTADO COJEDES: Cerro Azul, Fila La Blanquera, 1300 m elev. (09°57'50"N, 68°36'50"W). 26 February 1979. Alfredo Paolillo. Museo de Historia Natural La Salle (MHNLS 7519–29). Verified by Celsa Seóaris. First state record and southernmost record for the species (La Marca 1992, Cuad. Geog. 9, Univ. Los Andes, Mérida. 197 pp.). This species seems to have had a more continuous distribution in the Venezuelan coastal range in the past, but now there is enough evidence of decline to indicate that its populations are seriously threatened (La Marca and Reinthaler 1991, Herpetol. Review 22:125–128; La Marca 1995, Reptilian Magazine 3[8]:22–24; La Marca and Létters 1997, Herpetologia Bonnensis. Pp. 207–213).

Submitted by **GILSON RIVAS FUENMAYOR**, Museo de Historia Natural La Salle, Apartado 1930, Caracas 1010-A, Venezuela.

COCHRANELLA PLUVIALIS. BOLIVIA: LA PAZ: Provincia Nor-Yungas, Cerro Uchumachi near Coroico (16°10'S, 67°42'W), 1950 m elev. 17 January 1998. Steffen Reichle. Verified by Wolfgang Böhme. Colección Boliviana de Fauna, La Paz (CBF 3302). Found at night in an area of disturbed cloud forest, together with another glassfrog species, *Hyalinobatrachium bergeri*. First record for Bolivia; southeastward range extension (airline) of ca. 550 km (Cannatella and Duellman 1982, Herpetologica 38:380–388).

Submitted by **JÖRN KÖHLER**, Zoologisches Forschungsinstitut und Museum Alexander Koenig, Adenauerallee 160, 53113 Bonn, Germany, and **STEFFEN REICHLE**, Langwiesenstrasse 26, 70771 Leinfelden-Echterdingen, Germany.

FROSTIUS PERNAMBUCENSIS. BRAZIL: ALAGOAS: Murici Forest Reserve, Fazenda Bananeiras, 9°14'S, 35°48'W, 700 m elev. 16 July 1997. Eliza Freire, Selma Torquato, Edelmo Gonçalves and Oswaldo Peixoto. Eugenio Izecksohn Collection, Herpetological Collection of Instituto de Biologia, Universidade Federal do Rio de Janeiro (EI 9344). Verified by Eugenio Izecksohn. Previously known only from the type locality; extends range ca. 170 km SW and also significantly increases elevation range of the species (type locality is at sea level). First record for the state. One male specimen found in the water tank of a ground bromeliad in a remaining patch of the Atlantic Forest formation.

Submitted by **OSWALDO LUIZ PEIXOTO**, Departamento de Biologia Animal Instituto de Biologia, Universidade Federal Rural do Rio de Janeiro, 23851-970, Seropédica, Rio de Janeiro, Brazil, and **ELIZA M. X. FREIRE**, Departamento de Zoologia, Universidade Federal de Alagoas, 57021-090, Maceió, Alagoas, Brazil.

HYLA DUTRAI. BRAZIL: ALAGOAS: Quebrangulo Municipality (9°19'S, 36°28'W), 366m elev. 26–29 March 1997. S. P. C. Silva and A. M. P. T. C. Silva. Universidade Federal do Rio de Janeiro (ZUFRJ 7173). April 1997. A. Studare. ZUFRJ 7174. Both verified by S. P. de Carvalho e Silva. Previously known only from type locality, Areia Branca, state of Sergipe (10°45'S, 37°18'W), (Gomes and Peixoto, 1996. Iheringia Ser. Zool. 80:33–38). Extends range ca. 200 km north; new record for the state, suggesting that as in other species of the *marmorata* group in northeastern Brazil, *Hyla dutrai* has a wider distribution than previously

reported. Record based on two males (SVL 33, 34.9 mm) allows the first confirmation of the distinguishing red color present in living specimens, extending across the lower belly region to the undersides of thighs.

Submitted by **M. R. GOMES**, Instituto de Biologia, Universidade Federal do Rio de Janeiro, Cidade Universitária, Rio de Janeiro, 21941-590, Brazil, and **O. L. PEIXOTO**, Instituto de Biologia, Universidade Federal Rural do Rio de Janeiro, Seropèdica, Rio de Janeiro, 23851-970, Brazil.

MELANOPHRYNISCUS STELZNERI FULVOGUTTATUS (Redbelly Toad). BRAZIL: MATO GROSSO DO SUL: Bela Vista Municipality (ca. 22°02'S, 56°30'W). 22 January 1967. E. Izecksohn and J. Jim. Museu de História Natural, Universidade Estadual de Campinas (ZUEC 3470); Jardim Municipality (ca. 21°28'S; 56°10'W). 7 July 1973. Unknown collector. ZUEC 3518; Caracol Municipality (ca. 22°00'S; 57°00'W). 20 October 1997. D. Pazzoto, Jr. ZUEC 11510. All verified by Ariovaldo A. Giaretta. First records of the subspecies in Brazil and of the genus in western Brazil. This race was previously known from Paraguayan Chaco, Formosa (central Chaco), Resistencia (austral Chaco), and Corrientes in Argentina (Cei 1980, Monit. Zool. Ital. (N.S.) Monogr. 2:1–609).

Submitted by **MARCELO NOGUEIRA DE CARVALHO KOKUBUM**, Universidade Estadual Paulista, IBILCE, Rua Cristóvão Colombo s/n, 15054-000, São José do Rio Preto- São Paulo, Brazil, and **PAULO SÉRGIO BERNARDE**, Curso de Pós-Graduação em Zoologia, Departamento de Zoologia, Universidade Federal do Paraná, CP 19020, 81531-990, Curitiba-PR, Brazil; e-mail: bernarde@garoupa.bio.ufpr.br.

PEDOSTIBES TUBERCULOSUS (Malabar Tree Toad). INDIA: GOA: Cotegao Wildlife Sanctuary,15°30'N, 73°55'E. 26–28 October 1994. Romulus Whitaker. ZSI A8894. Verified by Shyamal K. Chanda. Adult male found ca. 1.5 m up on a tree adjacent to a stream within a riparian forest. General forest type was wet evergreen in a lowland situation. Species is restricted to the Western Ghats of southwestern India, being recorded from only a few localities in the southern ranges of the Ghats-Malabar, Ponmudi, Vanjikadavu, and Silent Valley, all within the southern state of Kerala (Dutta 1997, Amphibians of India and Sri Lanka: Checklist and Bibliography. Odyssey Publ. House, Bhubaneswar. 342 pp.; Pillai 1986, Rec. Zool. Surv. India 84:229–242; Inger et al. 1984, J. Bombay Nat. Hist. Soc. 81:406–427), and not reported from the Union Territory of Goa (Sekar 1991, Herpeton Pune 4:14–15; 1991, J. Bombay Nat. Hist. Soc. 88:125–127; 1992, J. Bombay Nat. Hist. Soc. 89:134–135). Present record is an extension of the species' range by ca. 750 km to the north, and suggests its presence in the intervening state of Karnataka.

Submitted by **INDRANEIL DAS** and **ROMULUS WHITAKER**, Centre for Herpetology, Madras Crocodile Bank Trust, Post Bag 4, Mamallapuram, Tamil Nadu 603 104, India.

CROCODYLIA

CAIMAN LATIROSTRIS (Broadsnout Spectacled Caiman, Jacaré do Papo Amarelo). BRAZIL: ALAGOAS: Matriz do Camaragibe (09°09'06"S 35°32'00"W). 18 February 1986. D. M. Teixeira. Museu Nacional, Universidade Federal do Rio de Janeiro (MNRJ 6446). Verified by Ronaldo Fernandes. First record for the state; extends range of the southern populations ca. 1000 km airline NNE. Previously known from the states of Bahia, south to the state of Rio Grande do Sul and in the northeastern states of Pernambuco and Rio Grande do Norte. A recent revision (Medem 1983, Los Crocodylia de Sur America. Vol. 2) attributes the discontinuity of the populations to lack of appropriate collecting.

Submitted by **GUILHERME V. DE SOUZA** and **THAIS S. DE FREITAS**, Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, Rio de Janeiro, 20940-040, Brazil.

TESTUDINES

KINOSTERNON SCORPIOIDES (Scorpion Mud Turtle). BRAZIL: RORAIMA: 4°10'45"N, 61°0'46"W, Km 681 on the Boa Vista–Pacaraima Road. 16 August 1997. William E. Magnusson. Photograph digitized on CD-ROM and deposited in the Reptilia Collection of the Instituto Nacional de Pesquisas da Amazónia, Manaus, Brazil (Registration number 1523). Verified by Richard C. Vogt. Species has been recorded from widespread localities in South America, but not previously from the state of Roraima in Brazil, or any part of the Rio Negro drainage basin (Iverson 1992, A Revised Checklist with Distribution Maps of the Turtles of the World. Privately printed. Richmond, Indiana. 363 pp.).

Submitted by **WILLIAM E. MAGNUSSON, ALBERTINA P. LIMA**, and **MARIA CARMOZINA DE ARAUJO**, Coordenaño de Pesquisas em Ecologia, Instituto Nacional de Pesquisas da Amazónia, CP 478, 69011-970 Manaus AM, Brazil.

PSEUDEMYS CONCINNA SUWANNIENSIS (Suwannee River Cooter). USA: FLORIDA: Taylor and Dixie Cos: Steinhatchee River, Sec. 19, T9S, R10E, just upstream of town of Steinhatchee, ca. 8 km upstream from river mouth on Gulf of Mexico, but within tidal influence. 22 April 1998. Dale R. Jackson and Michael A. Ewert. UF 113442 (subadult female, specimen and slides) and UF 113441 (first-year juvenile, color slides) collected by basking traps. Verified by David L. Auth. On the same day we observed from a small motorboat ca. one dozen basking *Pseudemys* (estimated carapace lengths 50–350 cm) in the next 6 km upstream; most appeared to be *P. concinna,* although the capture of a *P. f. floridana* (UF 113443, specimen and slide) at the same basking site as the two specimens above makes long-distance identification problematic. Taylor Co: Spring Creek, a tributary of the Fenholloway River at U.S. Rt. 98 (Sec. 31, T4S, R7E). June 1960. M. A. Ewert. Color photographs of adult female, UF 112988, collected and released. Verified by D. L. Auth. Site confirmation was verified 21 April 1998 based on existence of old railroad trestle (photographed in 1960) as well as physiographic features; DRJ earlier reported (Jackson 1997, Herpetol. Rev. 28:94) our mistaken identification of the site as the Econfina River crossing, ca. 20 km west on U.S. Rt. 98. Spring Creek is one of the few unpolluted sections of this river system, which otherwise has been degraded by four decades of industrial effluent that appears to have nearly extirpated the cooter population (although *Trachemys scripta* and *Apalone ferox* seem to have fared better). However, continued survival was confirmed 21–23 October 1997 by DRJ, who observed and photographed at a distance a basking adult *P. concinna* in the lowermost section of the river (Sec. 36, T5S, R5E), ca. 2 km inland from the Gulf of Mexico; though subject to strong tidal fluctuation, the river there is largely fresh, albeit polluted.

New drainage records (Jackson 1992, *in* P. Moler (ed.), Rare and Endangered Biota of Florida, Vol. 3. Amphibians and Reptiles, pp. 166–170. Univ. Press Florida, Gainesville; Jackson 1995, Chelonian Cons. Biol. 1:329–333) that broaden the known distribution of the species in the series of "small rivers" draining directly into the Gulf of Mexico between the Aucilla and Suwannee

rivers. Coupled with the previous report for the Econfina River (Jackson 1997, *op. cit.*), the Steinhatchee and Fenholloway river records virtually eliminate the conjectured disjunction between peninsular and panhandle populations of this species, which had been used by some to hypothesize separate specific identities for those populations (reviewed by Jackson 1995, *op. cit.*).

SERPENTES

AGKISTRODON CONTORTRIX CONTORTRIX (Southern Copperhead). USA: FLORIDA: SANTA ROSA CO: SE 1/4 Sec. 31, T6N, R27W, in Blackwater River State Forest ca. 1.5 km south of the Escambia County (Alabama) line. A male (57.0 cm snout-vent length; 7.1 cm tail) collected from a gully-eroded first-order stream valley in a mature southern temperate hardwood forest. 19 April 1998. Grayal Farr and D. B. Means. Two 35mm slides cataloged together as UF 112975. ESCAMBIA CO: 4.8 km W Brynville on Fla. Road 4. 14 April 1968. F. H. Kaiser. UF 74422 (formerly FSU 439). Both verified by David L. Auth. First records for Santa Rosa and Escambia counties, and unequivocally establishes that the species occurs in Florida outside of the Apalachicola River Valley. The Escambia Co. record and an unverified report from Okaloosa Co. (roadkill on Florida Road 189, 0.8 km S of the Covington Co., Alabama, state line. Jim Godwin. Ca. 1984. Specimen not saved. Paul E. Moler, pers. comm.) were previously noted as dots on a published range map of the species, but the above data were not given (Means 1992, Rare Southern Copperhead, *in* P. E. Moler (ed.), Rare and Endangered Biota of Florida. Volume III. Amphibians and Reptiles, pp. 242–246. University Press Florida, Gainesville.).

Submitted by **D. BRUCE MEANS**, Coastal Plains Institute and Land Conservancy, 1313 North Duval Street, Tallahassee, Florida 32303, USA.

CHIRONIUS QUADRICARINATUS QUADRICARINATUS. BRAZIL: BAHIA: Canavieiras (15°40'S, 38°39'W). 25 June 1990. A. J. S. Argólo. Coleção Zoológica Gregório Bondar by Centro de Pesquisas do Cacau/CEPLAC (CZGB 1058); 30 August 1992. A. J. S. Argólo. CZGB 2066; Itapicurá (11°19'S, 38°13'W): June 1993. Paulo Cardoso. CZGB 2453. All verified by Ronaldo Fernandes. In Brazil, subspecies occurs in the Campos Cerrados of the states of Mato Grosso, Minas Gerais, Bahía, and Goiás (Dixon et al. 1993, Mus. Reg. Sci. Nat. Tor. Monografie XIII). These authors have examined only one specimen from Bahia, which has no specific locality data. The two localities cited here certify the occurrence of the taxon in the cerrado ecosystem (northern Bahia) and "restinga" (sea shore vegetation, eastern Bahia).

CROTALUS MOLOSSUS MOLOSSUS (Blacktail Rattlesnake). USA: TEXAS: Gillespie Co.: AOR, 4.1 mi N Willow City on Willow City loop road. 30 August 1997. Christopher R. Harrison. UTEP 17520. Verified by Carl S. Lieb. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **CHRISTOPHER R. HARRISON**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA, and **TRAVIS J. LaDUC**, Texas Memorial Museum and Department of Zoology, The University of Texas at Austin, Austin, Texas 78712-1064, USA.

ECHINANTHERA AFFINIS. BRAZIL: BAHIA: Vitória da Conquista (14°51'S; 40°50'W). 5 July–31 December 1995. Coleção Zoológica Gregório Bondar by Centro de Pesquisas do Cacau/CEPLAC (CZGB 4241–43); 1 January to 31 October 1996. CZGB 4724–25. All collected by L. dos Santos. Verified by R. Fernandes. Species is found in southeastern and southern Brazil, from southeastern Minas Gerais through Espírito Santo, Rio de Janeiro, São Paulo, Paraná, and Santa Catarina, to northeastern Rio Grande do Sul (Di-Bernardo 1992, Comun. Mus. Ciénc. PUCRS, sér. zool. 5:225–256). All specimens were found in Atlantic seasonal forest, 941 m elev. First record for the state of Bahía and the northermost record for this species.

Submitted by **ANTÓNIO JORGE SUZART ARGÓLO**, Laboratório de Ofiologia, Centro de Pesquisas do Cacau/CEPLAC, Km 22 Rodovia Ilháus-Itabuna, CEP 45600-000, Ilháus, Bahia, Brasil, and Universidade Estadual de Santa Cruz, Km 16 Rodovia Ilháus-Itabuna, CEP 45650-000, Ilháus, Bahía, Brazil.

All verified by Ronaldo Fernandes. Subspecies is known from the Atlantic slopes of the coastal range of southeastern Brazil, from the state of Paraná to Espírito Santo (Hoge and Romano 1975, Mem. Inst. Butantan 39:51–60). According to these authors, it should occur also at Bahia. These are the first records of *D. i. petersi* for Bahia, extending its distribution over 600 km north to Soretama (Linhares), which was its northern limit in the literature.

Submitted by **FÁTIMA QUEIROZ ALVES**, Departamento de Zoologia, Instituto de Biologia, UNESP, CEP 18618-000, Rubião Jr, Botucatu, São Paulo, Brazil, and **ANTÓNIO JORGE SUZART ARGÔLO**, Laboratório de Ofiologia, Centro de Pesquisas do Cacau/CEPLAC, Km 22 Rodovia Ilhéus-Itabuna, CEP 45600-000, Ilhéus, Bahia, Brazil, and Universidade Estadual de Santa Cruz - UESC, Km 16 Rodovia Ilhéus-Itabuna, CEP 45650-000, Ilhéus, Bahia, Brazil.

DRYADOPHIS CLIFTONI (Clifton's Lizard Eater). MÉXICO: NAYARIT: Santa María del Oro lagoon, 800 m elev. (21°21'43"N, 104°34'08"W). November 1991. Paulino Ponce-Campos. Universidad Autonoma de Guadalajara (COHERP-UAG-R-243). Verified by H. M. Smith. First record for the state (listed in error, Flores Villela and Gerez 1994, Biodiversidad y Conservacion en México: p. 319; correctly listed by those authors for Sinaloa, but omitted from Sonora, Durango, and Jalisco, for all of which records are available in the literature). Only one record is known for Jalisco (Hardy 1963, Copeia 1963:669–672), near Talpa; we photographed one (COHERP-UAG-R-418) from 161 air km E Talpa at Barranca de Oblatos-Huentitan, municipality of Guadalajara, 100 m elev., 300 m NW Arcediano bridge on Rio Santiago, 20 m from the river, 20°44'54"N, 103°22'43"W. 20 October 1996. Paulino Ponce-Campos. Verified by H. M. Smith.

Submitted by **PAULINO PONCE-CAMPOS** and **SARA M. HUERTA-ORTEGA**, Bosque Tropical A. C., Apartado Postal 5-515, Gaudalajara, Jalisco 45042, México.

ELAPHE GUTTATA (Corn Snake). USA: LOUISIANA: Allen Parish: Louisiana Rt. 26, 0.1 mi NW Rt. 147, 5.7 mi NW of Calcasieu River. 24 April 1996. Steve Shively. LSUMZ 57630; 1 mi S jct. U.S. Rt. 190 and Topsy-Bel Road. 17 April 1998. Avery A. Williams. Seale Museum of Louisiana, McNeese State University (SML 9316); 6 mi S jct. U.S. Rt. 190 and Topsy- Bel Road. 22 April 1998. Avery A. Williams. SML 9317; Topsy-Bel Road, 3 mi N Texas Eastern Road (parish line). 26 April 1998. Kirk Manuel. SML 9318; U.S. Rt. 190, 2.1 mi W LeBlanc. 2 May 1998. Kirk Manuel (SML 9320); Jefferson Davis Parish: Topsy area, on Topsy-Bel Road. 1 May 1998. Kirk Manuel. SML 9319. All verified by Jeff Boundy. First parish records. These records extend the distribution of this species to the southwest from Vernon, Rapides, and Evangeline parishes as mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA.

FARANCIA ABACURA (Mud Snake). USA: FLORIDA: FRANKLIN CO: St. Vincent Island on Insulator Road, 100 m NW of site B (NE 1/4 Sec. 30, T9S, R9W). 20 March 1983. S. P. Christman. UF 55865 (large road-killed adult); site A (NW 1/4 Sec. 11, T10S, R9W) on the SE edge of the island near Oyster Pond. 22 April 1983. S. P. Christman. UF 55622 (hatchling trapped in a drift fence bucket); on Road E6 (SE 1/4 Sec. 34, T9S, R9W). 14 August 1997. R. Cordray. UF 112482 (road-killed gravid female, 13 left and 3 right oviducal ova >3.0 cm long, 119.0 cm snout-vent length, 13.7 cm tail). Judging by the fact that there were only 3 large ova and about 9 additional vascularized areas in the right oviduct, this female had recently oviposited part of her clutch of about 25 eggs. All specimens verified by David L. Auth. First records for any of the eastern Gulf Coast barrier islands of Apalachee Bay (Blaney 1971, Herpetologica 27:406–430).

Submitted by **D. BRUCE MEANS**, Coastal Plains Institute and Land Conservancy, 1313 North Duval Street, Tallahassee, Florida 32303, USA, and **STEVEN P. CHRISTMAN,** Route 3, Box 2831, Quincy, Florida 32351, USA.

HETERODON NASICUS (Western Hognose Snake). MÉXICO: AGUASCALIENTES: municipality of Aguascalientes (21°57'N, 102°17'W) in grassland and dry forest. 1 November 1991. Gilfredo de la Riva. Universidad Autónoma de Aguascalientes, Centro Básico, Departamento de Biología [UAA(VR) 00209]. Verified by Carlos Balderas. First record for state of Aguascalientes; extends range ca. 160 km SE of Zacatecas, 210 km SW of San Luis Potosí (Platt 1969, Univ. Kansas Publ. Mus. Nat. Hist. 18:253–420) and 125 km NW of Jalisco (Pérez-Ramos 1987. Herpetol. Rev. 18:56).

Submitted by **JOEL VAZQUEZ-DIAZ** and **GUSTAVO QUINTERO-DIAZ**, Universidad Autónoma de Aguascalientes. Centro Básico, Departamento de Biología, Avenida Universidad 940, C.P. 20100, Aguascalientes, Aguascalientes, México, and **AURELIO RAMIREZ-BAUTISTA**, Instituto de Biología, Departamento de Zoología, Universidad Nacional Autónoma de México, Apartado Postal 70-153, México Distrito Federal 04510, México.

HETERODON PLATIRHINOS (Eastern Hognose Snake). USA: GEORGIA: DECATUR CO: 5.6 km NW Faceville. 5 September 1954. S. A. Minton and P. W. Smith. INHS 7616. Verified by Jeanne M. Serb. New county record (Williamson and Moulis 1994, Distribution of Amphibians and Reptiles in Georgia. 2 Vols. Savannah Sci. Mus. Spec. Publ. 3:1–712).

Submitted by **JOHN E. PETZING** and **CHRISTOPHER A. PHILLIPS**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

IMANTODES GRACILLIMUS (Slender Blunthead Tree Snake). MÉXICO: JALISCO: Cajón de Peña Dam, Rio Tomatlán, municipality of Tomatlán, 135 m elev. (19°59'N, 105°11'W). July 1991. Local collector for Paulino Ponce-Campos. Universidad Autonoma de Guadalajara (COHERP-UAG-R-230). Verified by H. M. Smith. First record for the state; previously recorded from Nayarit (Islas Tres Marias), Colima, Michoacan, and Guerrero.

Submitted by **PAULINO PONCE-CAMPOS** and **SARA M. HUERTA-ORTEGA**, Bosque Tropical A. C., Apartado Postal 5-515, Gaudalajara, Jalisco 45042, México.

LAMPROPELTIS CALLIGASTER CALLIGASTER (Prairie Kingsnake) USA: TEXAS: MORRIS CO: DOR 1.6 km N of Naples on a county road. 19 April 1997. Toby J. Hibbitts. TCWC 78776. Verified by James R. Dixon. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **TOBY J. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA.

LAMPROPELTIS CALLIGASTER OCCIPITOLINEATA (South Florida Mole Kingsnake). USA: FLORIDA: DESOTO CO: Arcadia. Late March 1995. Chuck Hurt. UF 112928. Verified by David Auth. Offspring from gravid female collected from wild. New county record; extends range ca. 96.5 km W of previous documented locality.

Submitted by **KENNETH L. KRYSKO**, Department of Wildlife Ecology and Conservation, University of Florida, Gainesville, Florida 32611, USA, e-mail: kenneyk@grove. ufl.edu, and **CHUCK HURT**, P.O. Box 234, Nocatee, Florida, USA.

LAMPROPELTIS GETULA HOLBROOKI (Speckled Kingsnake). USA: MISSOURI: DOUGLAS CO: DOR, Missouri Rt. 181 near jct. with Missouri Rt. AP. 10 September 1993. C. A. Phillips. INHS 11221. Verified by Jeanne M. Serb. New county record (Johnson 1987, The Amphibians and Reptiles of Missouri. Publ. Missouri Dept. Conserv., Jefferson City. 368 pp.; Powell et al. 1993, Missouri Herpetol. Assoc. Newsl. 6:3–31).

Submitted by **CHRISTOPHER A. PHILLIPS** and **JOHN E. PETZING**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820.

LAMPROPELTIS GETULA NIGRA (Black Kingsnake). USA: OHIO: VINTON CO: within city limits of Wilksville. 12 April 1995. David C. Sapienza. KU Color Slides 11259–260. Verified by Travis W. Taggart. A threatened species in Ohio; was documented from a nature preserve, thus the specimen was not collected. Female, ca. 48 inches in total length; laid 9 eggs in spring of 1995. New county record, and the northernmost record in Ohio.

Submitted by **JOSEPH T. COLLINS**, The Center for North American Amphibians and Reptiles, 1502 Medinah Circle, Lawrence, Kansas 66047, USA, and **DAVID C. SAPIENZA**, Lake Hope State Park, 27331 State Route 278, McArthur, Ohio 45651, USA.

LIOPHIS POECILOGYRUS SCHOTTI. BRAZIL: MARANHÃO: Presidente Dutra - BR 226, Km 48. Fazenda São Pedro. 10 December 1985. Museu Paraense Emélio Goeldi (MPEG 17673). Verified by Rubens N. Yuki. Species is found in the Amazon Rainforest-Cerrado-Caatinga (Dixon and Markezich 1992, Texas J. Sci. 44:131–166). This is the first record for the state of Maranhão.

Submitted by **NELSON RUFINO**, Laboratório de Herpetologia, Museu Paraense Emílio Goeldi, Campus de Pesquisa, Avenida Perimetral, Guamó, Caixa Postal 399, CEP: 66.017-970. Belém, Pará, Brazil.

MASTICOPHIS FLAGELLUM (Coachwhip). USA: LOUISIANA: ALLEN PARISH: 1 mi W Reeves on U.S. Rt. 190. 17 July 1971. Jim Roberts. LSUMZ 76325; Kinder area. 13 March 1967. Jerry G. Walls. Seale Museum of Louisiana, McNeese State University (SML 1502); 3.5 mi S U.S. Rt. 190 on Topsy-Bel Road. 7

May 1998. Avery A. Williams. (SML 9321). All verified by Jeff Boundy. First parish records. These specimens fill the gap between Beauregard and Evangeline parishes as mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana. Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA.

MICRURUS COLLARIS (Coral Snake). BRAZIL: AMAPÁ: Cachoeira Santo Antônio (00°40'S, 52°30'W), Rio Jarì (01°09'S 51°54'W). 19 May 1987. Museu Paraense Emélio Goeldi (MPEG 17871). Verified by Rubens N. Yuki. This species is known from southeastern Venezuela and the Guianas (Campbell and Lamar 1989, The Venomous Reptiles of Latin America. Cornell Univ. Press, Ithaca, New York. 425 pp.). According to Campbell and Lamar (*op. cit.*), there is a disputed record from the state of Pará. This is the first record for the state of Amapá.

Submitted by **NELSON RUFINO**, Centro de Referéncia em Educaõ Ambiental Professor Eidorfe Moreira, Escola Bosque, Avenida Nossa Senhora da Conceiõ, s/n. Cep: 66.815-590, Belém (Outeiro), Pará, Brazil.

OXYBELIS AENEUS (Mexican Vine Snake). MÉXICO: AGUASCALIENTES: "El Tepozan," Municipality of Calvillo (21°58'N, 102°45'W), in subtropical dry forest. 11 August 1982. Gilfredo de la Riva. Universidad Autónoma de Aguascalientes, Centro Básico, Departamanto de Biología (UAA[VR] 00094). Verified by Mario Mancilla. First record for Aguascalientes; extends range ca. 75 km NE of Zacatecas (Keiser 1974, Bull. Texas Mem. Mus. 22:1–51), 175 km NW of Guanajuato (Duges 1896, Naturaleza 2:479–485), and 350 km NW of Queretaro (Dixon et al. 1972, Southwest. Nat. 16:225–237).

Submitted by **JOEL VAZQUEZ-DIAZ** and **GUSTAVO QUINTERO-DIAZ**, Universidad Autónoma de Aguascalientes. Centro Básico, Departamento de Biología. Avenida Universidad 940, C.P. 20100, Aguascalientes, Aguascalientes, México; and **AURELIO RAMIREZ-BAUTISTA**, Instituto de Biología, Departamento de Zoología, Universidad Nacional Autónoma de México, Apartado Postal 70-153, México Distrito Federal 04510, México.

PHALOTRIS LEMNISCATUS. ARGENTINA: CORRIENTES: Departamento Mburucuya: Parque Nacional Mburucuya (27°59'S, 57°58'W). 12 November 1996. J. A. Cespedez and R. H. Aguirre. Colección Herpetológica de la Universidad Nacional del Nordeste, Corrientes, Argentina (UNNEC 05776). Verified by B. B. Alvarez. First vouchered record for Argentina (mentioned as probable by Lema 1984, Iheringia Ser. Zool. Porto Alegre 64:66–68; Cei 1993, Mon. XIV Mus. Reg. Sci. Nat. Torino 550–552; and Williams and Francini 1991, Bol. Mus. Reg. Sci. Nat. Torino 9[1]:64). Other countries where species has been recorded are Brazil and Uruguay (Ferrarezzi 1993, Dissertacao de Mestrado, Curso Pos-grad. Instituto Biociencias, USP. 277 pp.; Puorto and Ferrarezzi 1993, Mem. Inst. Butantan, 55[1]:40–44).

Submitted by **EDUARDO FEDERICO SCHAEFER**, Anatomia Comparada, Departamento de Biologia, Facultad de Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, 9 de julio 1449, 3400 Corrientes, Argentina; e-mail: schaefer@unefcen.edu.ar.

PITUOPHIS CATENIFER SAYI (Bullsnake). USA: MINNESOTA: Carlton Co: Split Rock Twp., 15 km W Moose Lake (SWSW Sec. 24, T46N, R21W). 12 September 1996. Leonard and Sandra Pasek. JFBM 13512. Verified by James Underhill. County record (Oldfield and Moriarty 1994, Amphibians and Reptiles Native to Minnesota. Univ. Minnesota Press, Minneapolis. 237 pp.). Extends the range ca. 100 km north.

Submitted by **JOHN J. MORIARTY**, Hennepin Parks, 3800 County Road 24, Maple Plain, Minnesota 55359, USA.

PSEUSTES SHROPSHIREI. VENEZUELA: DISTRITO FEDERAL: Canales de Naiguatá, vertiente Norte del Parque Nacional Avila, 720 m elev. (10°35'N, 66°40'W and 10°38'N, 66°50'W). 8 May 1989. Daniel Lew. Museo de Historia Natural La Salle (MHNLS 11400). Verified by María José Praderio. First state record. ESTADO CARABOBO: Valle, entre la entrada y Cerro el Café, Valencia (10°17'N, 68°07'W). 5 May 1989. Marco Aleman. Colección de Vertebrados Universidad Experimental Rómulo Gallegos (CVUNERG 125). Verified by Marco Natera. First state record. Captured in gallery (riverine) forest. ESTADO MIRANDA: Parque Nacional Guatopo, 400 m elev. (10°05'N, 66°25'W). 19 August 1965. José M. Pelaez. MHNLS 1644. Verified by Celsa Seóaris. First estate record. ESTADO ZULIA: San José de los Altos, Sierra de Perijó, 1460 m elev. (10°55'56"N, 72°26'22"W). July 1975. Francisco Delascio. Verified by Celsa Seóaris. MHNLS 6249). First state record.

MHNLS 1644, 11400, and CVUNERG 125 are the only confirmed records of this species east of the Andes. Species was previously known from Venezuela on the basis of two specimens (Museo de Ciencias Naturales de Caracas, MCNC 3622, 4896) taken in the state of Táchira (Las Mesas, entre la Grita y La Fría, 08°10'08"N, 72°09'50"W (Rivas and Molina 1996, Resúmenes del IV Congreso Latinoamericano de Herpetología, Santiago, Chile: 292).

Submitted by **GILSON RIVAS FUENMAYOR**, Museo de Historia Natural La Salle, Apartado 1930, Caracas 1010-A, Venezuela, and **CÉSAR R. MOLINA R.**, Postgrado en Biología, mención Ecología, Facultad de Ciencias, Universidad Central de Venezuela, Caracas, Venezuela; e-mail: cmolina@strix.ciens.ucv.ve.

REGINA RIGIDA SINICOLA (Gulf Crayfish Snake) USA: TEXAS: Morris Co: 6.4 air km N and 0.8 air km E Omaha. 19 April 1997. Terry L. Hibbitts. TCWC 78749. Verified by James R. Dixon. New county record (Dixon 1987, Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **TOBY J. HIBBITTS**, Department of Wildlife and Fisheries Sciences, Texas A&M University, College Station, Texas 77843, USA and **TERRY L. HIBBITTS**, 602 Hilltop circle, Wylie, Texas 75098, USA.

SIBON NEBULATA. BRAZIL: ALAGOAS: Rio Largo (ca. 9°30'S; 35°50'W) in a small patch of Atlantic Forest. 13 September 1996. Collected by Eliza M. X. Freire. Museu de História Natural da Universidade Federal de Alagoas (MUFAL 1361) and Museu Nacional da Universidade Federal do Rio de Janeiro (MNRJ 6344). Verified by Ronaldo Fernandes. First record for the state; these specimens extend the range of the species ca. 1500 km southeast of Belém, Pará, Brazil (Cunha and Nascimento 1978, Publ. Avul. Mus. Par. Emílio Goeldi 31; Kofron 1990, Amphibia-Reptilia 11:207–223).

Submitted by **ELIZA MARIA XAVIER FREIRE**, Departamento de Zoologia e Museu de História Natural, Universidade Federal de Alagoas, Rua Aristeu de Andrade 452, Maceió, Alagoas, 57021-090, Brazil, and Departamento de Vertebrados, Museu Nacional, Universidade Federal do Rio de Janeiro, Rio de Janeiro, 20940-090, Brazil.

SIMOPHIS RHINOSTOMA. BRAZIL: BAHIA: Vitória da Conquista, Baixa da Taboa Farm (15°15'S, 41°09'W). 1 August–19 November 1997. W. S. Dutra. Colección Zoológica Gregório Bondar by Centro de Pesquisas do Cacau/CEPLAC (CZGB 5874). Verified by R. Fernandes. Species is found in dry districts in the south-central section of Brazil (Amaral 1978, Serpentes do Brasil. Second ed. Melhoramentos/Universidade de São Paulo, São Paulo. 246 pp.). First record of species for the state of Bahía, extending its range into northeastern Brazil.

Submitted by **ANTÓNIO JORGE SUZART ARGÓLO**, Laboratório de Ofiologia, Centro de Pesquisas do Cacau/CEPLAC, Km 22 Rodovia Ilháus-Itabuna, CEP 45600-000, Ilháus, Bahía, Brazil, and Universidade Estadual de Santa Cruz, Km 16 Rodovia Ilháus-Itabuna, CEP 45650-000, Ilháus, Bahía, Brazil.

TANTILLA MELANOCEPHALA. ARGENTINA: PROVINCIA DE CORRIENTES: Departamento Mburucuyú: Area Natural Protegida Mburucuyú (28°00'S, 58°00'W). 24 March 1994. S. Montanelli. Colección Herpetológica Corrientes, Universidad Nacional del Nordeste, Corrientes, Argentina (UNNEC 4988). Verified by Alejandro Giraudo. First record with precise locality for Argentina. The species was reported from the Argentinian provinces of Corrientes, Misiones, Gran Chaco, and Uruguay, and the northern areas of South and Central America (Koslowsky 1898, Rev. Mus. La Plata 8:197; Seriá 1921, Ann. Soc. Cient. Argentina 92:165; Seriá 1936, Inst. Mus. Obra Cincuent. 51; Peters and Orejas Miranda 1970, Bull. U.S. Nat. Mus. 297:295; Avalos and Mischis 1975, Bol. Acad. Nac. Cienc. Córdoba 51[1–2]:72), but without reference to collected material.

Submitted by **SILVANA MONTANELLI**, Protected Area Mburucuyú, C. C. 1, 3427 Mburucuyú, Corrientes, Argentina, and **BLANCA BEATRIZ ALVAREZ**, Cátedra de Anatomía Comparada, Departamento de Biología, Facultad Ciencias Exactas y Naturales y Agrimensura, Universidad Nacional del Nordeste, 9 de julio 1449, 3400 Corrientes, Argentina.

MICHAEL J. BLANFORD
P.O. Box 3436, Carbondale, Illinois 62901, USA

Numerous contributions to the Geographic Distribution section of *Herpetological Review* have been made by Illinois herpetologists in the 1990s, especially by Tucker (1994, Herpetol. Rev. 25:79–80) and Redmer and Ballard (1995, Herpetol. Rev. 26:49–53). Specimens reported herein are housed in the following collections: Field Museum of Natural History (FMNH), Illinois Natural History Survey (INHS) and Southern Illinois University at Carbondale (SIUC). County records were verified by checking the Illinois Herpetological Vouchered Database, located at the Illinois Natural History Survey, which contains data on Illinois amphibian and reptile species from thirty U.S. collections. Using information from the database, a web page was developed to provide county-level distribution data for amphibians and reptiles in Illinois. This web site can be accessed via the following URL:

http://www.inhs.uiuc.edu/cbd/main/misc/herp/herp.html

The database can be searched in either species mode or county mode. Distribution maps or county species lists may be printed out for field reference or other relevent uses.

CAUDATA

Ambystoma opacum (Marbled Salamander). FAYETTE CO: 8 km NW St. Peter, pond W side Co. Rd. 1700E and 0.75 km S Little Hickory Creek (SE 1/4 SE 1/4 NE 1/4 Sec. 11, T5N, R2E; UTM Zone 16: N4306160m, E331855m). 13 March 1997. J. E. Petzing and M. J. Dreslik. Verified by C. A. Phillips. INHS 13306. New county record.

Ambystoma talpoideum (Mole Salamander). POPE CO: 1 km W New Liberty on New Liberty-Unionville Road (NW 1/4 Sec. 17, T16S, R7E). 11 April 1995. M. Redmer and K. Cook. Verified by R. A. Brandon. SIUC H-5517. First specimen from county; confirms previous record of Klimstra and Hutchison (1965, Trans. Illinois State Acad. Sci. 58:151–156), which lacks a voucher. Collected alive on road along a swamp.

Ambystoma texanum (Smallmouth Salamander). CHRISTIAN CO: 2.6 km S Willeys at the Flat Branch (SW 1/4 Sec. 17, T13N, R1W;

UTM Zone 16: N4382300m, E308700m). 26 March 1997. C. A. Phillips and J. E. Petzing. Verified by J. M. Serb. INHS 12932. New county record; JASPER Co: 3 km S Hidalgo, E side Illinois Rt. 130 and just S Co. Rd. 1900N (NE 1/4 NW 1/4 Sec. 19, T8N, R10E; UTM Zone 16: N4331000m, E401230m). 20 March 1997. C. A. Phillips and J. E. Petzing. Verified by J. M. Serb. INHS 13285. New county record; MCDONOUGH Co: 8 km NE Macomb at East Fork LaMoine River (SE 1/4 Sec. 16, T6N, R2W; UTM Zone 15: N4485425m, E701610m). 1 May 1997. J. E. Petzing, S. B. Amundsen, W. C. Handel and J. E. Hofmann. Verified by C. A. Phillips. INHS 12990. New county record; WILL Co: NE side of main entrance to McKinley Woods Forest Preserve (SE 1/4 SW 1/4 SE 1/4 Sec. 30, T34N, R9E). 5 June 1996. J. DalPonte and D. Mauger. Verified by C. A. Phillips. INHS 12589. New county record.

Ambystoma tigrinum (Eastern Tiger Salamander). ALEXANDER Co: 1.5–2 km NW Diswood on Diswood-McClure Road (NE 1/4 Sec. 4, T15S, R2W). 26 March 1995. M. Redmer and K. Tolch. Verified by R. A. Brandon. SIUC H-5504. New county record. AOR; FAYETTE Co: 0.5 km S Vandalia (NE 1/4 Sec. 21, T6N, R1E). 24 May 1994. C. A. Phillips, J. M. Serb and F. T. Burbrink. Verified by K. S. Cummings. INHS 11264. New county record; POPE Co: Brownfield. 13 May 1950. P. W. Smith and W. L. Burger. Verified by C. A. Phillips. INHS 4958. Series of 12 larvae. County record that was not plotted in Smith (1961, Bull. Illinois Nat. Hist. Surv. 28:1–298); POPE Co: jct. of Homberg and Golconda to Bay City Roads (south center of S 1/2 Sec. 10, T14S, R6E). 5 March 1995. M. Redmer and K. Cook. Verified by R. A. Brandon. SIUC H-5507. AOR. This record is included because of the specific locality data and because the specimen is an adult.

ANURA

Bufo americanus (American Toad). WARREN Co: 1.6 km NW Monmouth, trib Cedar Creek at Co. Rd. 2100N (NE 1/4 Sec. 24, T11N, R3W; UTM Zone 15: N4534100m, E695800m). 9 September 1997. J. E. Petzing, C. A. Phillips, K. S. Cummings and C. A. Taylor. Verified by J. M. Serb. INHS 13317. New county record.

Acris crepitans (Northern Cricket Frog). CHRISTIAN Co: Lake Sangchris State Park. 6 June 1991. M. Bavetz. Verified by R. A. Brandon. SIUC H-4537. New county record; CLINTON Co: 6.4 km NNW Frogtown at Co. Rd. 1850N along Shoal Creek (NW 1/4 Sec. 24, T3N, R4W; UTM Zone 16: N4285590m, E282663m). 15 April 1997. J. E. Petzing and C. A. Phillips. Verified by J. M. Serb. INHS 12978. New county record; DEWITT Co: 4 km NE Kenney, Ten Mile Creek at Co. Rd. 500E (border between NE 1/4 SE 1/4 Sec. 2 and NW 1/4 SW 1/4 Sec. 1, T19N, R1E; UTM Zone 16: N4443930m, E325540m). 19 October 1996. J. E. Petzing and K. S. Petzing. Verified by C. A. Phillips. INHS 12782. New county record; DOUGLAS Co: Villa Grove, Embarras River at Illinois Rt. 130 (SE 1/4 SE 1/4 Sec. 3, T16N, R9E; UTM Zone 16: N4413410m, E400710m). 20 October 1996. J. E. Petzing. Verified by C. A. Phillips. INHS 12785. New county record; EDWARDS Co: 5 km E West Salem, Bonpas Creek at Co. Rd. 1900N (NW 1/4 NW 1/4 Sec. 14, T1N, R14W; UTM Zone 16: N4264400m, E417600m). 1 October 1996. C. A. Phillips and J. E. Petzing. Verified by J. M. Serb. INHS 12720. New county record; HENRY Co: 3.2 km S Colona at Big X interchange (NW 1/4 Sec. 25, T17N, R1E). 22 September 1994. C. A. Phillips. Verified by J. M. Serb. INHS 11391. New county record. Confirms literature record [Garman 1892, Illinois Lab. Nat. Hist. Bull. 3(13):215–388]; MCDONOUGH Co: 8 km NE Macomb at the East Fork LaMoine River (NE 1/4 Sec. 21, T6N, R2W; UTM Zone 15: N4485600m, E701451m). 9 October 1996. J. E. Petzing, C. A. Phillips and C. A. Taylor. Verified by J. M. Serb. INHS 12751. New county record.

Pseudacris crucifer (Spring Peeper). SCHUYLER Co: 5 km S Industry, West Branch Sugar Creek at U.S. Rt. 67 (NE 1/4 Sec. 11, T3N, R2W; UTM Zone 15: N4458400m, E704320m). 9 October 1996. J. E. Petzing, C. A. Phillips and C. A. Taylor. Verified by J. M. Serb. INHS 12771. New county record.

Pseudacris triseriata (Western Chorus Frog). LAWRENCE Co: Red Hills State Park, first ravine along U.S. Rt. 50 in the northern part of the park. 15 October 1994. M. Bavetz, M. Blanford and M. Redmer. Verified by R. A. Brandon. SIUC H-4762. New county record; MCDONOUGH Co: 8 km NE Macomb at East Fork LaMoine River (NE 1/4 Sec. 21, T6N, R2W; UTM Zone 15: N4485600m, E701451m). 9 October 1996. J. E. Petzing, C. A. Phillips and C. A. Taylor. Verified by J. M. Serb. INHS 12752. New county record.

Rana areolata (Crawfish Frog). ALEXANDER Co: 1.5–2 km NW Diswood on Diswood-McClure Road (NE 1/4 Sec. 4, T15S, R2W). 26 March 1995. M. Redmer and K. Tolch. Verified by R. A. Brandon. SIUC H-5508. New county record. AOR; MASSAC Co: 2 km E Unionville on Unionville-New Liberty Road (west center of Sec. 14, T16S, R6E). 5 March 1995. M. Redmer and K. Cook. Verified by R. A. Brandon. SIUC H-5506. New county record. AOR; UNION Co: 4 km NE Dongola in front of "Christian Church" (NW 1/4 Sec. 17, T13S, R1E). 24 May 1997. M. Redmer. Verified by R. A. Brandon. SIUC H-5542. New county record.

Rana blairi (Plains Leopard Frog). HENDERSON Co: 4.4 km S Gladstone at trib Carthage Lake (SE 1/4 Sec. 28, T10N, R5W; UTM Zone 15: N4521500m, E671600m). 10 September 1997. J. E. Petzing, K. S. Cummings, C. A. Phillips and C. A. Taylor. Verified by J. M. Serb. INHS 13331. New county record; MCDONOUGH Co: 8 km NE Macomb at the East Fork LaMoine River (NE 1/4 Sec. 21, T6N, R2W; UTM Zone 15: N4485600m, E701451m). 9 October 1996. J. E. Petzing, C. A. Phillips and C. A. Taylor. Verified by J. M. Serb. INHS 12753. New county record; SCHUYLER Co: 3 km NW of Beardstown, Coal Creek Ditch at U.S. Rt. 67 (NW 1/4 Sec. 25, T1N, R1W; UTM Zone 15: N4435232m, E716252m). 10 October 1996. J. E. Petzing, C. A. Phillips and C. A. Taylor. Verified by J. M. Serb. INHS 12772. New county record.

Rana catesbeiana (Bullfrog). DEWITT Co: 9.5 km S LeRoy, Voegtlin's Pond (impoundment of tributary North Fork Salt Creek) (SE 1/4 SE 1/4 Sec. 19, T21N, R4E; UTM Zone 16: N4457340m, E347990m). 23 April 1997. J. E. Petzing, C. A. Phillips and C. E. Backe. Verified by J. M. Serb. INHS 12988. New county record; MORGAN Co: 9 km WNW Jacksonville at Mauvaise Terre Creek (NE 1/4 Sec. 9, T15N, R11W; UTM Zone 15: N4405140m, E729210m). 23 August 1996. R. E. DeWalt and R. S. Steinberg. Verified by C. A. Phillips. INHS 12645. New county record; TAZEWELL Co: 1.6 km N Cloverdale, tributary Farm Creek at U.S. Rt. 150 (NE 1/4 Sec. 2, T25N, R4W; UTM Zone 16: N4502800m, E287150m). 9 July 1997. J. E. Petzing, C. A. Phillips and K. S. Cummings. Verified by J. M. Serb. INHS 13168. New county record; WOODFORD Co: 3 km N Germantown Hills (NW 1/4 SE 1/4 Sec. 17, T27N, R3W; UTM Zone 16: N4518905m, E291115m). 24 September 1997. J. E. Petzing and C. A. Taylor. Verified by C. A. Phillips. INHS 13334. New county record.

Rana clamitans (Green Frog). HENDERSON Co: 6 km NE Gulfport and just S Lone Tree, Co. Rd. 900E at trib Carthage Lake (SE 1/4 SE 1/4 Sec. 24, T10N, R6W; UTM Zone 15: N4522300m, E667000m). 9 September 1997. C. A. Phillips, J. E. Petzing, C. A. Taylor and K. S. Cummings. Verified by J. M. Serb. INHS 13327. New county record; TAZEWELL Co: 3.2 km NE Harvard

Hills at tributary of Tenmile Creek (E 1/2 SE 1/4 Sec. 4, T26N, R3W). 9 July 1997. J. E. Petzing, C. A. Phillips and K. S. Cummings. Verified by J. M. Serb. INHS 13152. New county record.

Rana palustris (Pickerel Frog). VERMILION CO: 4.4 km E Georgetown at the former Peabody Coal site, now the Harry "Babe" Woodyard State Natural Area (Illinois Department of Natural Resources) (NE 1/4 SW 1/4 Sec. 2, T17N, R11W; UTM Zone 16: N4423500m, E451100m). 12 June 1996. J. E. Petzing and C. A. Phillips. Verified by J. M. Serb. INHS 12496. New county record.

Rana pipiens (Northern Leopard Frog). IROQUOIS CO: 4.8 km N Watseka, 0.3 km S jct. Co. Rd. 2200N and Co. Rd. 2100E (NE 1/4 Sec. 17, T27N, R12W; UTM Zone 16: N4519800m, E438400m). 2 April 1997. J. E. Petzing and C. A. Phillips. Verified by J. M. Serb. INHS 12944. New county record.

Rana sphenocephala (Southern Leopard Frog). CLINTON CO: 6.4 km NNW Frogtown, Co. Rd. 1850N along Shoal Creek (NW 1/4 Sec. 24, T3N, R4W; UTM Zone 16: N4285590m, E282663m). 15 April 1997. J. E. Petzing and C. A. Phillips. Verified by J. M. Serb. INHS 12977. New county record; EDWARDS CO: 4.5 km E West Salem, Bonpas Creek floodplain on S side Co. Rd. 1900N (NW 1/4 NW 1/4 Sec. 14, T1N, R14W; UTM Zone 16: N4264480m, E417700m). 20 March 1997. C. A. Phillips and J. E. Petzing. Verified by J. M. Serb. INHS 12922. New county record; MCDONOUGH CO: 8 km NE Macomb at East Fork LaMoine River (NE 1/4 Sec. 21, T6N, R2W; UTM Zone 15: N4485600m, E701451m). 9 October 1996. C. A. Phillips, J. E. Petzing and C. A. Taylor. Verified by J. M. Serb. INHS 12757. New county record.

Scaphiopus holbrookii (Eastern Spadefoot). PULASKI CO: 1.5 km W Ullin (NE 1/4 Sec. 27, T14S, R1W). 30 May 1997. M. Redmer. Verified by R. A. Brandon. SIUC H-5541. New county record. DOR.

TESTUDINES

Chelydra serpentina (Common Snapping Turtle). GALLATIN CO: Long Pond, 6 km N Old Shawneetown and 4 km W Ohio River (SE 1/4 Sec. 9, T9S, R10E; UTM Zone 16: N4178790m, E402830m). 17 June 1994. M. J. Dreslik and E. O. Moll. Verified by C. A. Phillips. INHS 12745. New county record.

Chrysemys picta (Painted turtle). CRAWFORD CO: 4.2 km W Annapolis, Maple Creek at Co. Rd. 2000N (NE 1/4 NW 1/4 Sec. 16, T8N, R13W; UTM Zone 16: N4332950m, E425165m). 7 October 1996. L. M. Page, R. S. Steinberg, T. Kompare and M. Pyron. Verified by C. A. Phillips. INHS 12795. New county record; HARDIN CO: 2 km W Cave-In-Rock (NW 1/4 Sec. 23, T12S, R9E; UTM Zone 16: N4146700m, E395000). 24 May 1997. C. A. Phillips, L. R. Phillips and L. Schultz. Verified by J. M. Serb. INHS 13277. New county record.

Graptemys pseudogeographica (False Map Turtle). GALLATIN CO: Round Pond, 7 km N Old Shawneetown (NW 1/4 Sec. 10, T9S, R10E; UTM Zone 16: N4179400m, E403170m). 16 June 1994. M. J. Dreslik and E. O. Moll. Verified by C. A. Phillips. INHS 12820. New county record. HARDIN CO: 2 km W Cave-In-Rock at Herrin Club (NW 1/4 Sec. 23, T12S, R9E; UTM Zone 16: N4146700m, E395000m). 24 May 1997. C. A. Phillips, L. R. Phillips and L. Schultz. Verified by J. M. Serb. INHS 13017. New county record.

Pseudemys concinna (Eastern River Cooter). GALLATIN CO: Round Pond, 7 km N Old Shawneetown (NW 1/4 Sec. 10, T9S, R10E; UTM Zone 16: N4179400m, E403170m). 17 June 1994. M. J. Dreslik and E. O. Moll. Verified by C. A. Phillips. INHS 12746. New county record. This species is listed as endangered in Illinois and has only been sight/photo vouchered from Gallatin County (Moll and Morris 1991, Trans. Illinois State Acad. Sci. 84:77–83).

Trachemys scripta (Slider). DUPAGE CO: Downers Grove, 1 km E Lemont Road at I-55. 23 June 1988. M. Redmer and J. Cobula. Verified by C. A. Phillips. INHS 10775. New county record; FAYETTE CO: 6.1 km S Herrick (39°9'29"N, 88°58'38"W). 21 July 1992. A. K. Wilson. Verified by R. A. Brandon. SIUC R-2711. New county record; MARSHALL CO: Illinois Rt. 26, 0.5 km S jct. with Co. Rd. 115N (SW 1/4 Sec. 23, T29N, R3W). 30 September 1994. T. Anton and D. Mauger. Verified by A. Resetar. FMNH 251614. New county record. DOR on Illinois Rt. 26; WILL CO: Training area of the Joliet Arsenal (NW 1/4 Sec. 14, T34N, R9E). 27 August 1993. M. Redmer and R. Humbert. Verified by A. Resetar. FMNH 251323. New county record.

Kinosternon flavescens spooneri (Illinois Mud Turtle). HENRY CO: Frankenreider Farm, 5 km N of Annawan (SE 1/4 Sec. 22 and SW 1/4 Sec. 23, T17N, R5E; UTM Zone 16 N4591200m, E258000m). 1993. M. Tuma. Verified by C. A. Phillips. INHS 12811. New county record. Carapace and plastron only.

Kinosternon subrubrum (Eastern Mud Turtle). ALEXANDER CO: 4 km S Sandusky and ca. 0.04 km W Illinois Rt. 127 jct. with unnamed road (NE 1/4 Sec. 36, T15S, R2W). 16 April 1994. K. Tolch and C. Oyler. Verified by R. A. Brandon. SIUC R-2925. New county record. DOR.

Apalone mutica (Smooth Softshell). FAYETTE CO: 6.1 km S Herrick (39°9'53"N, 88°58'11"W). 16 July 1992. A. K. Wilson. Verified by R. A. Brandon. SIUC R-2710. New county record.

Apalone spinifera (Spiny Softshell). FAYETTE CO: 6.1 km S Herrick (39°9'35"N, 88°58'35"W). 4 September 1994. A. K. Wilson. Verified by R. A. Brandon. SIUC R-2712. New county record; WILL CO: Joliet Army Training Area on Baseline Road bridge, 60 m S Jackson Creek (Sec. 24, T34N, R9E). 29 August 1993. T. Anton and M. Redmer. Verified by A. Resetar. FMNH 251297. New county record. Hatchling DOR on Baseline Road.

SAURIA

Ophisaurus attenuatus (Slender Glass Lizard). IROQUOIS CO: 0.8 km NW Leesville (NE 1/4 NE 1/4 Sec. 1, T29N, R11W; UTM Zone 16: N4542800m, E454400m). May 1994. E. Richter. Verified by C. A. Phillips. INHS 12565. New county record. DOR on a sandy road.

SERPENTES

Diadophis punctatus (Ringneck Snake). FAYETTE CO: 2.75 km S Herrick at the Russ Tate residence (NW 1/4 Sec. 33, T9N, R2E; UTM Zone 16: N4339180m, E328345m). 9 June 1993. R. Tate and J. E. Petzing. Verified by R. A. Brandon. SIUC R- 2879. New county record. Found under a piece of tin on side of a hill close to the edge of a oak-hickory forest. Specimen was kept in captivity until it died in June 1995; HENDERSON CO: 6 km NE Gulfport and just S Lone Tree, SW corner Chicago, Burlington and Quincy RR and Co. Rd. 900E (NE 1/4 NE 1/4 Sec. 25, T10N, R6W; UTM Zone 15: N4522548m, E667105m). 27 May 1997. J. E. Petzing and W. C. Handel. Verified by C. A. Phillips. INHS 13169. New county record; SHELBY CO: NW corner of Stewardson, 1 km W of the Illinois Rt. 32/Norfolk and Western RR jct. (NW 1/4 SW 1/4 Sec. 34, T10N, R5E; 39°15'58"N, 88°37'59"W). 21 October 1996.

A. Manuel. Verified by C. A. Phillips. INHS 12822. New county record. DOR.

Elaphe obsoleta (Eastern Rat Snake). EDWARDS CO: 1.2 km W Bennington, drainage channel W of Little Wabash River at Co. Rd. 1850N (SE 1/4 Sec. 18, T1N, R10E; UTM Zone 16: N4263933m, E401055m). 1 October 1996. J. E. Petzing and C. A. Phillips. Verified by J. M. Serb. INHS 12744. New county record. Caught on top of a grassy levee; WOODFORD CO: Illinois Rt. 26, 1 km N Spring Bay at jct. with Zimmerman Road (NW 1/4 Sec. 1, T27N, R4W). 30 September 1994. T. Anton and D. Mauger. Verified by A. Resetar. FMNH 251610. New county record. DOR.

Heterodon platirhinos (Eastern Hognose Snake). FAYETTE CO: 3.1 km S Herrick (39°11'8"N, 88°59'8"W). 24 April 1994. M. Tate. Verified by R. A. Brandon. SIUC R- 2700. New county record. An adult female captured by Michael Tate laid 22 eggs on 21 June 1994. A hatchling mortality was taken as a voucher by A. K. Wilson.

Lampropeltis triangulum (Milk Snake). HARDIN CO: 2 km W Cave-In-Rock at Herrin Club (NW 1/4 Sec. 23, T12S, R9E; UTM Zone 16: N4146700m, E395000m). 24 May 1997. C. A. Phillips, L. R. Phillips and L. Schultz. Verified by J. M. Serb. INHS Herpetological Slide 1997-2. New county record. Specimen not vouchered because it was found in a protected area; MARSHALL CO: 7.2 km N Lacon on Illinois Rt. 26 (SW 1/4 Sec. 18, T30N, R2W). 30 September 1994. T. Anton and D. Mauger. Verified by A. Resetar. FMNH 251612. New county record. DOR.

Nerodia sipedon (Northern Water Snake). SHELBY CO: 3.6 km E Herrick and 0.5 km E Co. Rd. 1675E on Co. Rd. 3300N (SW 1/4 Sec. 13, T9N, R2E). 20 April 1996. J. E. Petzing. Verified by C. A. Phillips. INHS 12451. New county record. DOR.

Opheodrys aestivus (Rough Green Snake). FAYETTE CO: 3.1 km S Herrick (39°11'7"N, 88°59'8"W). 15 June 1994. R. Tate. Verified by R. A. Brandon. SIUC R-2701. New county record; FRANKLIN CO: Missouri-Pacific RR tracks at Illinois Rt. 149 (NE 1/4 Sec. 27, T7S, R1E). 14 September 1994. M. Blanford and M. Redmer. Verified by R. A. Brandon. SIUC R-2796. New county record.

Storeria dekayi (Brown Snake). MCDONOUGH CO: 8 km NE Macomb at East Fork LaMoine River (NE 1/4 Sec. 21, T6N, R2W; UTM Zone 15: N4485600m, E701451m). 9 October 1996. C. A. Taylor, C. A. Phillips and J. E. Petzing. Verified by J. M. Serb. INHS 12759. New county record.

Storeria occipitomaculata (Redbelly Snake). SHELBY CO: 5 km N Herrick and 6 km W Tower Hill/Herrick blacktop (SE 1/4 SW 1/4 Sec. 36, T10N, R1E). 29 October 1994. J. Calvert and N. Wilson. Verified by R. A. Brandon. SIUC R-2804. New county record.

Thamnophis proximus (Western Ribbon Snake). IROQUOIS CO: just E Iroquois County Conservation Area (NW 1/4 SW 1/4 Sec. 19, T29N, R10W). 22 July 1996. R. Milas and M. Pingleton. Verified by C. A. Phillips. INHS 12563. New county record.

Thamnophis radix (Plains Garter Snake). PUTNAM CO: Granville city limit, trash dump along Illinois Rt. 71 (NE 1/4 Sec. 9, T32N, R1W). 28 May 1994. D. Mauger. Verified by A. Resetar. FMNH 251604. New county record.

Thamnophis sauritus (Eastern Ribbon Snake). EDWARDS CO: 1.2 km W Bennington, Little Wabash River at Co. Rd. 1850N (SE 1/4 Sec. 18, T1N, R10E). 1 October 1996. C. A. Phillips and J. E. Petzing. Verified by J. M. Serb. INHS 12743. New county record. Juvenile found DOR on Co. Rd. 1850N.

Virginia valeriae (Smooth Earth Snake). FAYETTE CO: 3.1 km S Herrick (39°11'11"N, 88°59'15"W). 20 April 1994. C. Tate. Verified by R. A. Brandon. SIUC R-2702. New county record. Completes presumed range hiatus shown in Conant and Collins (1991, Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.). Record is on the northern limit of presumed range.

Acknowledgments.—We thank Kevin Cummings and Jeanne Serb for reviewing the manuscript. Field work by JEP and CAP was partially supported by a contract with the Illinois Department of Transportation. Field work by MR was supported by contracts with the Illinois Department of Natural Resources, the Nature Conservancy, and the United States Army. Field work by AKW, MR, and MJB was partially supported by the Illinois Department of Natural Resources Wildlife Preservation Fund, The Nature Conservancy, and the United States Department of Interior (U.S. Fish and Wildlife Service) contracts with R. A. Brandon. The *Kinosternon subrubrum* Alexander County record was collected by K. Tolch while under contract with the Illinois Department of Natural Resources and while using funds provided by the Chicago Herpetological Society.

The following new county records are from within the boundaries of the Tahoe National Forest, California. Localities for the six species were compared with the following references: Blanchard (1942), Ferguson (1961), Fitch (1938), Klauber (1972), Stebbins (1985), Wilson (1978), and Zweifel (1952, 1974); and the following museum collections: AMNH, BYU, CAS, Chico State University, CM, FMNH, KU, LACM, MCZ, MVZ, SDSNH, SSU, TNHC, UMMZ, University of Nevada (Las Vegas), UNR, USNM, and UTA (museum codes from Leviton et al. 1985). All specimens were verified by Robert C. Drewes.

Ambystoma macrodactylum (Long-toed Salamander). CALIFORNIA: NEVADA CO: Tahoe National Forest, pond along dirt road W of Eagle Lakes Rd, Sec. 23, T17N, R12E (39°19'56.1"N, 120°35'28.5"W, 1645 m). 16 May 1997. M. M. Tierney and J. V. Vindum. CAS 202865. Eleven larvae.

Coluber constrictor (Racer). CALIFORNIA: SIERRA CO: Tahoe National Forest, Yuba River, Hwy 49, 30 m below 18.27 mile marker, Sec. 36, T19N, R10E (914 m). 22 Jun 1997. M. M. Tierney. CAS 203365.

Crotalus viridis (Western Rattlesnake). CALIFORNIA: SIERRA CO: Tahoe National Forest, Humbug Creek, ca 100 m upstream from North Yuba Trail bridge (39°30'24.2"N, 120°57'58.0"W, 756 m). 17 May 1997. M. M. Tierney and J. V. Vindum. CAS 202876.

Diadophis punctatus (Ringneck Snake). CALIFORNIA: SIERRA CO: Tahoe National Forest, Kanaka Creek drainage, County Rd 191, 0.2–0.4 km E Kimberley Creek, SE 1/4 of SW 1/4 Sec. 5, T18N, R22E. 3 Sep 1997. M. M. Tierney. CAS 203485.

Elgaria coerulea (Northern Alligator Lizard). CALIFORNIA: SIERRA CO: Tahoe National Forest, S side Brandy City Pond, (39°32'37.7"N, 121°01'30.3"W, 1097 m). 25 July 1997. C. L. Spencer and J. V. Vindum. CAS 203344. C. L. Spencer and J. V. Vindum. 20 Aug 1997. CAS 203459. Gravid female with seven embryos (CAS 203460–466).

Lampropeltis zonata (California Mountain King Snake). CALIFORNIA: SIERRA CO: Tahoe National Forest, Hwy 49, 6.32 km E (by road) Yuba County line (39°31'06.1"N, 120°59'31.8"W). 13 May 1997. M. M. Tierney. CAS 202935. Hwy 49, 37.43 km E (by road) Yuba County line (39°34'13.9"N, 120°44'2.0"W). 17 May 1997. M. M. Tierney and J. V. Vindum. CAS 202889.

Although distribution maps (Basey 1976; Stebbins 1985; Zeiner 1988) indicate that these species should occur in the Tahoe National Forest, no previous voucher specimens were found for these counties. This lack of data is symptomatic of our current knowledge of the distribution of many species occurring in northern California. The distribution maps of Stebbins (1985) and Zeiner (1988) indicate that approximately 31 species are expected to occur in the Tahoe National Forest. However, only 24 are confirmed by voucher specimens. Further, enlarging our scope to consider the four counties of which Tahoe National Forest is comprised (Nevada, Sierra, Placer and Yuba Counties), 33 native species of amphibians and reptiles are known to occur based on museum records from thirteen collections including the four largest California collections (CAS, LACM, MVZ, SDSNH). Despite museum records dating back to 1876, twelve of these 33 species are known from five or fewer localities. Thus, species records are not only lacking, but many species with records are poorly documented.

The surprising lack of documentation may be attributed, in part, to the use of shaded distribution maps in publications. Shaded distribution maps belie the actual known occurrence of species as validated by voucher specimens. Often range maps are presumed to show documented distribution, when, in fact, these maps represent projected ranges based on the habitats in which the species are expected to occur. Without revisiting arguments set forth by Tucker (1995) on the drawbacks of shaded maps to show ranges, we would like to reiterate that shaded maps may inhibit investigation by researchers who assume that these maps represent a well-documented species distribution. We advocate efforts to validate the assumptions made in shaded distribution maps by further collecting of voucher specimens in unsurveyed areas.

Acknowledgments.—We thank Mark Jennings and the staff of the above mentioned museums. Funding for field work was provided by a Challenge Cost-Share Agreement between CAS and the U.S. Department of Agriculture, Forest Service, Tahoe National Forest (CCSA-05-97-17-024), and generous donations to the Department of Herpetology, CAS, from Emily Date and Malcolm Miller.

For the past ten years we have been collecting and receiving specimens of reptiles and amphibians mainly from the southern part of the state of Mato Grosso in western Brazil. Literature records on the herpetofauna of this state are old and scarce. Some of the published records are also imprecise; they do not mention detailed localities and were published at a time when "Mato Grosso" (or "Matto Grosso") referred to an area at least three times larger than today (as in Amaral 1925). Prior to 1944, that name was applied to a huge area, then divided into two new political units: the state of Mato Grosso and "Território do Guaporé" (subsequently named "Território de Rondônia," and the state of Rondonia presently). Mato Grosso was again divided in 1979, resulting in the two new states of Mato Grosso and Mato Grosso do Sul. In spite of this, authors in recent revisionary studies still tend to treat them as a single unit (as in Dixon et al. 1993).

A preliminary review of our collecting data and of herpetological material housed at the vertebrate collection of the Universidade Federal de Mato Grosso (UFMT) has revealed new state records for the state of Mato Grosso (as presently defined). There are also new locality records that, although not new for the state, considerably extend the known range of the species considered. We here report new records for one anuran, five lizards, and

four snakes. Acronyms for institutions housing material here mentioned (other than UFMT) follow Leviton et al. (1985). Anuran identity was verified by José P. Pombal Jr., and reptiles were verified by Marcos Di-Bernardo.

ANURA

Rana palmipes. TANGARÁ DA SERRA: Usina Hidrelétrica Juba I, Rio Juba (14°44'S, 58°06'W). March 1994. C. Strussmann. UFMT 2067. Published information on the species in Mato Grosso is restricted to the material obtained by Natterer at Vila Bela, extreme western part of the state (see Miranda-Ribeiro 1923; see also a distribution map in Hillis and de Sá 1988). Extends documented distribution in Mato Grosso ca. 270 km to the east.

LACERTILIA

Coleodactylus brachystoma. ITIQUIRA: "Prainha," Rio Correntes along the right bank (17°36'S, 54°49'W), under a fallen board. 31 October 1994. C. Strussmann. UFMT 2117; BARÃO DE MELGAÇO: under rocks in a forested low hill named "Ilha do Paraíso" (ca. 16°17'S, 55°53'W), situated between Chacororé and Chá Mariana bays. November 1994. C. Strussmann. UFMT 2199, 2217, 2233, 2235. According to Vanzolini (1970), *C. brachystoma* occurred in forested patches amidst cerrados in Goiás and Minas Gerais. Localities here reported extend documented range of species to the west, in excess of eight longitudinal degrees.

Gonatodes hasemani. JAURU: under a fallen log in an isolated relict of semideciduous forest along the right bank of Rio Jauru, about one kilometer up the Cachoeira da Fumaça (ca. 15°14'S, 58°44'W). 24 November 1994. C. Strussmann. UFMT 2203, male. A female was collected from a pitfall in a semideciduous forest along the left bank of Rio Guaporé (15°07'S, 58°58'W). November 1996. Collector unknown. UFMT 2502; VILA BELA DA SANTÍSSIMA TRINDADE: Fazenda São Francisco, Serra da Borda. A female was obtained from a pitfall in the gallery forest of Córrego Longa Vida (14°41'32"S, 59°39'43"W). 23 June 1997. Carlos de Sá Neves. UFMT 2575. Nascimento et al. (1988) stated that forests of Rondonia seemed to constitute the eastern limits for the species (see also Avila-Pires 1995). We here extend the distributional limits of this lizard to at least 260 km SE of the political frontier between the states of Rondonia and Mato Grosso.

Kentropyx viridistriga. POCONÉ: PARQUE NACIONAL DO PANTANAL: Porto Caracará (17°52'S, 57°27'W). On floating grasses and shrubs, in a seasonally flooded plain. August 1986. C. Strussmann and J. C. Dalponte. UFMT 0008, 0025, 0044. A specimen from "Matto Grosso" (without any additional information on locality) was mentioned and described by Gallardo (1962). Gallagher and Dixon (1992) did not mention any documented Brazilian record for *K. viridistriga* in their recent taxonomic revision of the genus, although they stated that the species is "probably restricted to flood plain systems of ...and western Brazil."

Lygodactylus wetzeli. CÁCERES: Curtume Tannery (16°03'S, 57°40'W). 15 January 1993. M. A. Carvalho, C. Strussmann, and M. I. Castrillon. ZUEC 1521, UFMT 1899. These specimens confirm the occurrence of *L. wetzeli* at Cáceres, mentioned with doubt by Smith et al. (1977). Only a small hatchling from Mato Grosso was available to those authors, who stated that "it is so diminutive that specific allocation is not certain from its own structure ..."

Prionodactylus eigenmanni. JAURU: amidst leaf litter in a semideciduous forest along the left bank of Rio Guaporé (15°07'S, 58°58'W). November 1996. C. Strussmann. UFMT 2506; 2541. First state record.

SERPENTES

Liophis longiventris. TANGARÁ DA SERRA: Usina Hidrelétrica Juba I, Rio Juba (14°44'S, 58°06'W). 1994. Collector and collection date unknown. UFMT 2085. The species was described by Amaral (1925) from the huge "Matto Grosso" region, without any additional explanation on the type locality. The only previous documented record for the state of Mato Grosso was mentioned by Dixon (1983) from the vicinity of the lower course of Rio das Mortes (12°51'S, 51°46'W) in the extreme eastern part of the state (about 650 km of the locality here cited).

Oxybelis fulgidus (Green Whip Snake). BARRA DO BUGRES: ESTAÇÃO ECOLÓGICA DE SERRA DAS ARARAS (15°39'S, 57°13'W), in the gallery forest along the left bank of Córrego Salobo. 16 September 1992. C. Strussmann and F. A. Machado. UFMT 1774. First documented record for state.

Micrurus paraensis (Pará Coral Snake). DENISE: (14°46'S, 57°05'W), Fazenda Rio Claro. 1992. Márcia Ferreira. UFMT 2413. First state record, extending known range of the species SE ca. 710 km from the nearest previous record in Ouro Preto do Oeste, eastern Rondônia (Cunha and Nascimento 1993). The specimen clearly fits the taxon usually treated as a subspecies of *M. psyches* (as in Campbell and Lamar 1989), but referred to as a distinct species and figured in Cunha and Nascimento (1993).

Micrurus surinamensis (Aquatic Coral Snake). NOVA OLÍMPIA: (14°47'S, 57°17'W), Fazenda Itamarati. Collector and collection date unknown. UFMT 2412. An additional locality from those depicted by Schmidt (1952), Campbell and Lamar (1989), and Roze (1996).

e-mail: jmitchel@richmond.edu

Few people have exerted as great an influence in the science of herpetology, public education, and zoo biology as Roger Conant. He has had two careers, zoo biology and academic/field herpetology, and he has excelled in both. Readers are fortunate to be given an inside look into the life of someone who has witnessed the many changes that have occurred during the better part of the 20th century.

This 8.5 x 11 inch autobiography has 64 chapters spanning the period of 1909 to the present, four essays, 18 short anecdotal stories, vignettes of 20 well known herpetologists and 15 zoo personalities, and 31 color and 155 black-and-white photographs. The stories in this book are an impressive collection of behind-the-scenes tales of a professional scholar, zoo curator, administrator, and adventurer. Conant's fluid writing style and his impeccable attention to detail make these stories entertaining as well as informative and historically accurate. I cannot begin to describe all the stories, the people with whom Conant has interacted, and the exciting adventures that fill this book. I will, however, briefly describe some interesting aspects of his life and note some of the captivating stories.

Conant was born in 1909 and lived most of his youth in New Jersey. After graduating from high school at 16, he obtained a part-time job at a private zoo. There he developed a keen interest in the zoo field while learning how to handle a diversity of animals. His primary career was in the zoo field, spending six years at the Toledo Zoo and the remainder of his career at the Philadelphia Zoo (1935–1973). A particularly interesting incident that occurred during his years at the Toledo Zoo, and one which was to affect him the rest of his life, was the bite Roger sustained from a speckled rattlesnake (*Crotalus mitchellii*). This chapter accounts in vivid detail how the doctor permanently disabled his left thumb by cutting through nerves and how he nearly lost his life to a nasty case of tetanus. While at Philadelphia, he served as curator of reptiles, chief of public relations, and ultimately, director. He gave weekly radio programs to the public about the zoo and its animals and wrote numerous stories for the zoo's magazines for over 33 years. In 1937, Conant toured many of the zoos in Europe to obtain insights into zoo methodology and promotion. While in Germany, he had to give the Nazi salute and utter "Heil Hitler" whenever he had to enter a building. What an experience that must have been!

Conant's zoo career ran parallel to his other major interests in herpetology. These include the first scholarly treatise on the reptiles of a single state (Ohio), numerous papers on the systematics of North American watersnakes and other species, development and production of three editions of the most widely read herpetology book in the world (the field guide to eastern amphibians and reptiles in the Peterson Field Guide series), and completion, with his life-long friend Howard Gloyd (and the assistance of his wife Kathryn), of a world-class treatment of the snake genus *Agkistrodon* published in 1990. He conducted extensive field work in the New Jersey Pine Barrens where he lived much of his adult life, in Delmarva, Big Bend Texas, and several parts of Mexico.

This autobiographical "field guide" is actually several books in one. It is a history of the zoo business, a review of herpetology as it developed in the 20th century, a series of adventure stories to exotic places, and a love story. Many people, many of whom contributed to the zoo world and scientific community in their own right, crossed Conant's path. Almost all of them are mentioned. The one- to three-page vignettes alone offer insights into the world of herpetology and zoos in times past. The stories in this book are brought to life by Conant's descriptions of events, animals, and people.

Three chapters under the title of "Attempting the Impossible" describe the difficulties and adventures Conant and his late wife, Isabelle Hunt Conant, endured during preparation of the first herp field guide for the Peterson series. Accurate color photography was not available in the early 1950s and the Conants had to rely on other methods. All the illustrations in the published plates are of animals in natural poses arranged by Conant and photographed in black and white and hand colored by his wife. Most of the stories about the field guide are about seeking photographs and information on all the amphibians and reptiles of eastern North America. The first edition appeared in 1958. The second, which appeared in 1975, expanded its coverage westward to cover the gap created by the western field guide that did not include parts of the midwest. Two additional chapters on herping in Big Bend and three on the New Jersey Pine Barrens add more stories related to the field guides.

Isabelle Hunt Conant died in 1976, a loss that is lamented over and over in this book. Conant visited Howard Gloyd soon thereafter and learned of Gloyd's own terminal illness. After his death, Conant married Gloyd's wife, Kathryn. They have been companions ever since, traveling all over the world in pursuit of information and specimens for the equally monumental book on the snake genus *Agkistrodon*, and vacationing in tropical countries.

Conant spent many months in Mexico over a span of 20 years, focusing largely on natricine snakes in isolated bolsons. The stories told in 15 chapters clearly demonstrate that this has long been one of his favorite places. He has since traveled to every conti-

nent except Antarctica; there are many stories about travel and wildlife in Africa, Asia, and South America.

Conant's ancillary essay entitled "Herpetology Then and Now" reveals how he developed his perspectives on science, the value of collections, herpetoculture, and systematics. His statement, "Herpetoculture is not herpetology" may not be taken well by some people, although Conant does explain his position.

Chapters at the end of the book cover Conant's concern about the changing environment and the changes in the herpetological and zoo worlds. He clearly laments the loss of habitat and wildlife he has witnessed in his lifetime. He blames most of it on human BREED and GREED, the title to a near final chapter. He believes strongly that many of society's ills are due to human overpopulation and bases his conclusions on an experiment with mice in a cage left to their own reproductive madness. But most of all, he misses his second wife with whom he spent most of his life. His concluding chapter suggests that he will retire from it all but in the end, he notes, "Oh, what the hell. I can't just loaf. I've still too many things to do. How many frequent flier miles do Kathryn and I still have available?" I expect that Roger Conant will continue to make contributions to herpetology in the coming years and travel to more exotic places. His biography is far from being complete.

I could go on for pages about the contents of this book but something should be said about the book itself. The paper is a little thin and some of the pages are crinkled; however, the two-column layout and the font size make it easy to read. I found only one computer error (massa-sauga, p. 35) and no obvious mistakes in photograph captions or layout. Unfortunately, there is no bibliography or index. I wish he would have at least provided a list of his own publications. The price is quite reasonable, especially for today's books of this size. I should note also that the Toledo Zoo underwrote the book financially and all proceeds from its sales go to that institution.

If you want to delve into how field herpetology and zoo biology were conducted over the past eight decades, if you want to read adventure and travel stories, or if you simply want to read a well-written book, then buy this one. Every herpetologist and zoo curator would benefit from Roger's historical perspectives and insights into the personalities of our predecessors. This book would be a valuable addition to your library.

Tales of Giant Snakes: A Historical Natural History of Anacondas and Pythons, by John C. Murphy and Robert W. Henderson. 1997. Krieger Publishing Company, Krieger Drive, Malabar, Florida 32950. ISBN 0-89464-995-7, x+221 pp. US $29.50.

Big things,
while still at large,
look much bigger
than they really are....
Paul Fountain (1902)

This is a wonderful book, quite literally a book full of wonders. The wonders begin with the front dust jacket: a photo of three yahoos (probably all Ph.D. herpetologists) acting as though they are attempting to restrain two anacondas that are acting, in turn, as though they are quite dead. The scene is a site of utter environmental devastation that makes an Army Corps of Engineers project look good. This photo is captioned: "Catching large anacondas for the Venezuelan anaconda project. William F. Holmstrom." Holmstrom appears from time to time in the rest of the text, and two of his papers are cited, but I could never find any explanation or description of the "Venezuelan anaconda project." I am left to conclude it is or was not the sort of thing any respectable person would care to be associated with.

The cover photo was shot from an angle to maximize the apparent sizes of the snakes, a technique noted by Murphy and Henderson elsewhere, as in the wondrous photo postcard reproduced on p. 32. Here a facial view and three loops of an anaconda dwarf two humans—tiny and out of focus—in the background. The dramatic effect is terrific, especially considering it dates from 1932. Given a good modern camera and a bright, sunny day (good depth of field), one could shoot a similar picture today using a dead garter snake. Little things, displayed just right, look much bigger—to our great delight.

There are lots more wonderful photos. For example, as a sort of logo punctuating sections of the book appears the picture of a Sumatran woman dragging a reticulated python. The snake's head dangles almost to her knees; its neck is draped over her shoulder; its body plunges to the ground at her heel; then the snake stretches out beyond that point for more than two times her height—and the end of the snake's tail is not even in the picture. What a woman!

Not only is this book wonderfully illustrated with 50 black-and-white photos, drawings from original accounts, trading cards, and handbills (and eight maps), but the text is wonderfully organized. The table of contents lists eight chapters: Introduction, Giants in the Landscape, How Big Do Giant Snakes Get?, Food and Feeding, Sex Among the Giants, Encounters, Attacks On Humans, and finally Exploitation, Populations, and Conservation. In the contents, each chapter is further divided into as many as 30 or more headings and subheadings, making it easy for the reader to zoom right to a particular item of interest such as: "Do Giant Snakes Eat Fruit?," "Charming Prey," "Aggregations," or "Postpartum Behavior." Thus, this is a well constructed reference book. (Beware, however: some of the juiciest bits on food and feeding may appear in Encounters or Attacks On Humans. Do not just refer to one place.) A more detailed index would be helpful.

Bear in mind that the title begins "Tales...," and tales there are—great chunks of them quoted straight from the explorers, missionaries, scientists, zoo collectors, medical doctors, and multitudes of liars (and not a few truth tellers) of every stripe: wonderful tales....

How about the dugout canoe of fellows who ate, at one sitting, a twenty-foot python and both the pigs it had swallowed? How many people can fit in one dugout canoe? Bah, that is nothing compared to the three gentlemen who ate also in one sitting—a 130 foot python. I would have had a hard time finishing my third even when I was in high school (my doctor has forbidden me to attempt such feats today; cholesterol, you know).

And speaking of eating, consider the quoted advice given to missionaries in Africa: "Remember not to run away, the python can move faster...You must let him swallow your foot. It is quite painless and will take a long time.... Wait patiently until he has swallowed about up to your knee. Then carefully take out your knife...." Of course, that is nothing compared to what the missionaries have gone forth to tell the local folks.

Short of UFO's and encounters with extraterrestrials, no area of "science" is so rife with great woolly yarns and colossal whoppers as the chronicles of giant snakes. Throughout this book, which

provides the biggest and best of them, Murphy and Henderson's voices of reason prevail. They clearly label the "absurd," the "flights of fancy," the "greatly exaggerated," and the "outrageous." So, how big do snakes really get? The authors do not know. "It is more fun" they say, "to argue and speculate..., and if we knew for certain...we'd no longer have reason to discuss such an entertaining and enjoyable topic."

Still, if I have one general complaint about this book, it is that the authors should have spent a bit more time on scientific investigation of size. The view that such effort is out of place in a book of "tales" is unacceptable because a lot of real science is included herein, recast from dry journals into lively narrative. I remember being present, some of the time, when Allen Greer (1974) was calculating crocodile lengths from the available bits and pieces, skulls and bones, in museum collections. The work was not dull; it could be written as a really good story. I miss an attempt to locate the largest actual museum specimens of giant snakes or to extrapolate sizes of giants from heads, or other parts, that actually exist. Perhaps someone will now take that up and see it through.

The bottom line, for me, is that no giant snake story claiming even 30 feet is credible. The largest actual specimen may have been "Colossus," a reticulated python said to have been 28.5 feet, that lived at the Pittsburgh Zoo at least until November 1956. But, alas, where is this specimen now? For me, it suffices to say that a reward for any snake over 30 feet, which has grown from $1,000 "many years ago" to $50,000 today, remains unclaimed.

The last chapter of this book is arguably the most important. It is packed with facts about human interactions with giant snakes, from the estimate that, in 1985, 884.5 miles of skins from the big four giant snakes were consumed by the leather industry, to the fact that reticulated pythons alone are consumed "at a rate that exceeds one-half million per year," even today. "The lack of baseline data...needs to be corrected...before these snakes are dangerously reduced or completely gone..." say Murphy and Henderson, and: "Including snakes, specifically the giants, in the emerging environmental ethic...appears to us to be particularly important."

This book is not without irksome errors. The subtitle could use tightening; the book is not constructed on a historical timeline. Spellcheck should have caught the likes of "assissted" (p. x) and "Brueni" (for Brunei, p. 128). However, no machine, but only good proof reading, could catch items like "after a violent struggle of two" (p. 124), or "the prayers of all suffers" (p. 175). The sentence beginning "He then makes the totally erroneous assertion that the tail does not have to be anchored...to an object for the snake to strike..." only comes out all right if you keep on reading and do not bog down on the idea that a snake's tail does have to be anchored. As Murphy and Henderson explain, it does not. There are too many incomplete or confusing sentences, but that is minor quibbling. One particularly unfortunate error is in Map 1, p. 8: Trinidad is left out of the range of the anaconda, even though there are lots of citations to and stories about anacondas on that island in the text.

This book should be extremely popular. It will appeal not just to herpetologists, but to the broadest audience of natural history and science readers. It will prove an invaluable reference in school libraries and should inspire young readers, both with what is known and unknown about its immensely popular subject, and with how real scientists document observations. Even us old pros who live or work within the ranges of giant snakes, and encounter them frequently in the wild, may look again with renewed interest and try to answer some of the fundamental questions about these magnificent creatures clearly called for in this book. "Is the last giant snake on the planet destined to end its life so someone can have a pair of python cowboy boots?" Not likely now that Murphy and Henderson have published.

To judge from the crowds at the live exhibits at recent SSAR meetings, amphibians and reptiles are becoming more popular, generally, as well as subjects for photography. The increases in popularity and photography of these creatures may relate to increased concern about biodiversity, the reports in the media of disappearing or deformed frogs, or even the increased number of books, like this one, concerned with herptiles.

How to Photograph Reptiles and Amphibians, by West and Leonard, consists of five sections. (Although it identifies four parts, "The Equipment," "Photographics," "Photographing Reptiles and Amphibians," and "Making a Good Photo Great," respectively, it has a photographic portfolio of the authors' work embedded between parts two and three. The portfolio section is no different than any of the other sections; it consists of text, photos, and photo captions). There are also "Acknowledgments," "Preface," and "Resources" sections, the latter listing references and sources of audio tapes and photographic equipment.

In "The Equipment," the authors discuss hardware and operations for cameras, lenses, flash equipment, support, and film, after which they propose an equipment "starter package" for someone interested in herp photography. Their presentation here is pretty basic, typical of books of this genre, and appears accurate, if occasionally simplified. "Photographics" discusses exposure and flash photography (which is either exposure or light, which is covered therein!). "Photographing Reptiles and Amphibians" is the one section in the book (exclusive of the portfolio) which deals specifically with herptiles. However, it really goes into little detail, suggesting field guides, natural history books and field work to increase your opportunities to find subjects; some of the information contained under the headings "Stalking" and "Photographing Difficult Subjects" is probably useful to the beginner. "Making a Good Photo Great" is mostly about the value of learning the biology of, and respecting, your subjects; there is approximately one page of discussion of composition.

Although this book has a paper cover, and we probably would not expect it to hold up forever as a field guide, it does have a

sewn binding and our copy has been through many reads, searches and flip-throughs without incident, so it should survive use as a reference. The printing job is good, and the photos in good register with apparently accurate color. Only one typo stood out; Tamaron for Tamron in the caption on p.18.

It is not especially easy for us to judge how well this book meets the authors' goal(s), since they never identify their audience, nor unequivocally identify their goal. To judge from the size and content, we assume that the book is aimed at someone who wants to photograph herps, but has little experience with photography. If "the primary emphasis of this book is on techniques for photographing amphibians and reptiles in nature" (p. ix), for beginners, the book should be reasonably useful and it is not expensive; it is also not an exhaustive treatment. However, the clearly promotional description on the back cover suggests an audience and goals that are not really attained. Given the authors' stated bias toward photographing wild subjects under natural conditions, this may be understandable. Still, there is no "thorough discussion of light" and, in our view, only an incomplete view of "making a good picture great."

Although, in general, we are less concerned with what is in the book than what is not there, a couple of things do merit discussion. The most important of these complaints concerns the illustrations. It does not seem to us as though the illustrations were photographed specifically for the text. There are no references in the text to the photos that illustrate particular points. If one searches around and reads all of the photo captions, it is often possible to find an illustration of a textual point, but that is a lot to ask of the reader. And, not infrequently, the locations of photos do not make it easy. For example, the caption of the photo of the tortoise on p. 2 mentions fill flash, which is not discussed in the text until p. 59; that for the salamander on p. 5 mentions using a tripod to allow slow shutter speed and small aperture, thus maximizing depth of field, a concept discussed on p. 35. A better system would have been to use the standard technique of photography magazines, where (often smaller) images of the same subject, photographed with only the target variable changed, are grouped on the same or opposing pages. This allows the reader to easily and clearly get the point. Another standard is to indicate the type of film used, since this could easily have as large an effect on the results as do equipment and exposure conditions, which they indicate. It is also a bit disingenuous for the authors to imply by repeated reference to the value of "natural pictures" or "stalking" (e.g., "we would rather have one excellent photograph of an animal exhibiting its natural behavior than one thousand posed portraits of captive animals." p.100) that they are not manipulating their subjects. We have enough experience with amphibians and reptiles to know that clean specimens and backgrounds are uncommon at best, and that, except for frogs, which almost always look good as they sit, most of the herps that you do find out in nature are not in aesthetically pleasing postures. Snakes are seldom in pleasing coils (e.g., pp. 28–31) and salamanders rarely have their tails attractively curled (e.g., p. 95). Even if they are doing it outside, the authors are cleaning, posing and staging more than they would appear to want you to know. For example, how is it that the salamander "on a log on the forest floor" on p. 63 is on exactly the same piece of background as the salamander "in a mossy rock outcrop" on p. 95?

For the most part, photographing herptiles is no different than any other close-up subject. Lighting, exposure, depth of field and focus are almost always problems to conquer. What makes herp photography most different is handling the herps. Barely more than one page of text ("Photographing Difficult Subjects" in their part four) discusses this topic. Perhaps the question to ask yourself is this: why am I photographing herps? If the reason one photographs herps is for the aesthetic or philosophical value, or the challenge, of meeting the animal on its terms, and the photographs are like one's journal of this experience, then whatever satisfies the photographer is fine. If, however, you are photographing to sell images, or to impress students, colleagues or editors, doing something for its purity probably will not work all of the time. Attractive, aesthetically pleasing backgrounds are required; they may be out in the habitat where you found the herp, but you will probably have to search for that special site. You may find that you have to arrange it. The goal is to be pleasing but biologically correct. Good poses are a part of composition; coiled snakes are more pleasing than kinked, elongate snakes and salamanders with long, thin tails look better with them looped around than stretched out straight. In order to photograph an entire subject when it is elongate, one must back away to a point where the background dominates the composition and the details of the subject are no longer clear. Clean animals look better than those with mud or leaf litter all over them. How does one get the subjects in such condition?

West and Leonard discuss lighting in several contexts in this book, but it always seems to be a contrast between the prized "natural light" and the "clinical" artificial light. With the exception of some discussion of fill flash (mostly as a way to put a highlight in the eye), there is virtually no discussion of modifying light, natural or otherwise. The need for depth of field and to stop motion make having as much light as possible critical in close-up photography. We do not understand why a tripod, which limits mobility and composition in close-up situations, is used with a flash, nor why flash pictures are so often shot at an aperture of f11. The cost of the latter is depth of field, apparent in many of the photo examples. In fact, the shallow depth of field apparent in many of the flash and tripod photos serves as testimonial to the need for a good TTL (through the lens, a reference to the metering system) flash, and learning to modify light. The goal is to have light from a flash not look like light from a flash! In this way, one gets the best of both worlds, apertures of f32 or f22 and pleasing light. Softboxes, reflectors and diffusers all allow the photographer to modify the light from a flash so that it looks like diffuse natural light, the ideal situation for close-up subjects; the latter two devices can be used to reduce the harshness of direct sun, too. We might add that, especially in portrait-style close-ups, the point of focus should be the eye, because the viewer is attracted to the animal's face. If depth of field is going to fail you, better that the focus trail off toward the rear of the subject, than that the face be soft.

The bottom line? *How to Photograph Reptiles and Amphibians* can serve as an inexpensive beginning for the novice herp photographer. We can agree with much of what West and Leonard say. We do have some concern about what is not in the book, however, even for novices. If it were us, we'd look for *John Shaw's Closeups in Nature* and spend a few (1–5) dollars more for a comprehensive reference. Very little that Shaw does not say about close-up photography as it relates to herps is found in West and Leonard's book.

Monitor Lizards: Natural History, Biology and Husbandry, by Daniel Bennett. 1998. Edition Chimaira, Frankfurt am Main. 352 pp. 64 color plates. Softcover. DM 88.00 (US $49.95). ISBN 3-930612-10-0. (Available from Bibliomania!, P.O. Box 58355, Salt Lake City, Utah 84158-0355, USA).

MICHAEL S. Y. LEE
Department of Biological Sciences, Monash University, Clayton, Melbourne, VIC 3168, Australia
e-mail: mike.lee@sci.monash.edu.au

This enthusiastically written and attractively presented book represents a labor of love from its author and publishing team. It is an extensively revised version of *A Little Book of Monitor Lizards*, published privately by Bennett three years ago. The text has been expanded considerably, the number and quality of the photographs are greatly improved, the binding is more professional, and recent references have been incorporated (many from 1997—an impressive achievement considering my review copy reached me after a long sea journey in December that year).

Several English-language books on monitors have been released recently (De Lisle 1996; Green and King 1993; Steel 1996), and inevitably there is some overlap between them. Bennett's book, by design and good fortune, manages to minimize this redundancy by focusing on areas relatively poorly covered by the others. There is a detailed section on captive care—much of it based on extensive personal experience—covering everything from selecting a healthy young monitor to converting a spare room into an enclosure when it grows up. Each of the 45 currently recognized species of monitor is given an extensive individual treatment, with illustrations and detailed discussion on taxonomy, morphology, distribution, natural history, and rearing. This section occupies most of the book and is easily the most detailed and well-referenced species-by-species account of varanids published. The author has done a remarkable job in surveying the scientific and semipopular literature for information on each species, and bringing it all together. Until now, it was impossible to find such syntheses except for a handful of well-known species. Similarly, the discussion of monitor folklore neatly summarizes widely scattered accounts of an area many herpetologists will find fascinating but of which they might otherwise be largely unaware.

Few others would have the time, interest, and persistence to cast their bibliographic nets so widely. The popularity of monitor lizards among reptile keepers and the general public has led to a plethora of articles in the semipopular literature, such as nature and terrarium magazines, and herpetological society newsletters. Important natural history information in such sources often escapes the attention of the scientific community. Conversely, scientific papers can be intimidating to lay people, yet often contain much information useful for reptile enthusiasts. Bennett has performed an immensely useful service by tracking down and synthesizing information from these widely scattered and often obscure sources and making it readily accessible to all readers. The coverage of scientific and semipopular references is truly impressive; even in the discussion of the fossil record of varanids (an area I thought I knew reasonably well), I came across citations of interesting papers of which I was unaware. One of the most valuable aspects of this book will no doubt be its extensive bibliography, containing over 1100 references.

Because the author's main interest, and the stated focus of the book, is on ecology and captive care, it is not surprising that the chapter on evolution and phylogeny is rather brief. The importance of precise taxonomic knowledge is rightly emphasized by Bennett throughout, but the recent explosion of work on the phylogenetic relationships of varanids is not adequately covered; there is a simple listing of putative subgeneric groups but no discussion (or tree diagram) of relationships within or between these groups. As well, many heterodox ideas are presented without supporting arguments: e.g., the striking similarities between varanids and snakes are clearly convergent (there is much evidence that they are homologous), and the success of monitors in Australia is attributed to facultative bipedality (the usual explanation is that scarce and unpredictable resources of this region favor reptiles over mammals). More serious are some factual errors: for instance, mosasaurs are reputed to grow up to 50 m (50 ft would be stretching it), and all anapsid reptiles except turtles are said to have perished 250 million years ago (procolophonoids survived for another 50 million years). Perhaps I found this section disappointing because of my strong interests and opinions in the area—the non-specialist reader will probably not notice or care too much!

The book is crammed with fascinating natural history anecdotes, many again based on the author's personal experience. Unfortunately, some of the more intriguing reports lack sources; readers would no doubt like to be able to track down the original references for themselves. For instance, the nares of Bengal monitors are said to close to a slit ontogenetically, accompanied by a change in foraging technique that involves poking the snout into the earth. Similarly, some monitors are said to disembowel prey with their foreclaws, and *Varanus prasinus* is said to occasionally copulate while dangling via only its prehensile tail.

Finally, some gloss is lost because of numerous spelling and grammatical errors scattered throughout the text. In particular, many references either are not listed, or cited under the wrong year (e.g., Philippen 1995 on p. 15; Orlov and Tuniev 1986 on p. 17; Baverstock et al. 1994 on p. 18). These typos are especially prevalent in the bibliography: on page 302 alone, for instance, such glitches afflict a dozen citations.

These problems are minor, however, and easily can be remedied in a future edition (which will be eagerly awaited). Until then, almost anyone interested in reptiles will want this book, which represents the most comprehensive, up to date, and reasonably priced of the current cohort of monitor books. It covers areas the others gloss over, and will be particularly useful for those interested the natural history and captive care of these spectacular lizards.

Sampling Amphibians in Lentic Habitats is an important reference for anyone conducting or thinking about conducting amphibian surveys. It expands on *Measuring and Monitoring Biological Diversity: Standard Methods for Amphibians* (Heyer et al. 1994) by providing tested, area specific techniques and field forms. The book is written for the Pacific Northwest, but is useful for anyone working in ponds and lakes. Much of the book is also useful for lotic habitats, although such habitats are not a focus of the book.

The book is organized into seven chapters written by some of the leading amphibian field people in the Northwest. In order, these chapters progress through all the necessary steps needed to conduct an amphibian inventory or monitoring program. Using this book, a general field biologist can design, setup, and report on a monitoring program. It is as close to a cookbook as an amphibian techniques manual can be. Although some people feel that "cookbooks" simplify too much, I believe that they are very useful to the non-specialist field biologist.

"Amphibian Inventory and Monitoring: A Standardized Approach for the PNW," by Olson and Leonard, is the introductory chapter that covers the reasons for conducting surveys and the requirement for the use of standardized methods. They emphasize the need for consistent and repeatable methods. The chapter also includes a table of distribution, habitats, and habits of the amphibians found in lentic habitats in the Pacific Northwest and examples of data collection forms.

"Design of Amphibian Surveys," by Gary M. Fellers, is an explanation of the various steps needed to successfully plan a survey. Most of the chapter may seem elementary to experienced surveyors, but it nicely explains the advantages and disadvantages of various items needed to plan and set up a survey. It is a good review even for those of us who think we know how to do a survey.

"Basic Amphibian Survey for Inventory and Monitoring in Lentic Habitats," by Chris Thoms, Charlotte C. Corkran, and Olson, takes one into the field with the survey plan from the previous chapter. The chapter is thorough and includes things like field safety and post-survey cleanup, as well as how to approach and divide up a site for surveying.

"Surveying and Monitoring Amphibians Using Aquatic Funnel Traps," by Michael J. Adams, Klaus O. Richter, and Leonard, provides details on the proper use of funnel traps for collecting amphibian larvae. They discuss the various types of traps and the problems with them. Although funnel traps are important in the detection of some salamander larvae, they still have some problems with detectability of select species. Funnel traps should be used in conjunction with other survey techniques.

"Integrated Sampling for Amphibian Communities in Montane Habitats," by R. Bruce Bury and Donald J. Major, presents the elements of an adaptive survey for dealing with remote and variable habitats. Using standard techniques the authors explain how to conduct surveys under non-standard situations, while still allowing for repeatability.

"A Habitat-based Method for Monitoring Pond-breeding Amphibians," by Charles M. Crisafulli, provides survey methods for wetlands and lakes that are too large for complete surveys, or for studies focused on selected habitat types. The author explains how to delineate habitat types and document their boundaries. The chapter also goes through the various methods that can be used in such specific habitats. These methods are very similar to those introduced in the Basic Surveys and Integrated Sampling chapters and help to enforce the basic techniques used in all surveys.

"Checklist for Amphibian Survey Reports," by Charles R. Peterson, gives a step by step procedure on how to prepare a final report of the survey data. The outline for the report is very complete and if followed should produce a thorough report. One nice addition would be a section on how to select the method of dissemination of reports by a government agency, professional journal, or other avenues.

A section of 40 color plates shows different lentic habitat types found in the Northwest—providing a good overview of the wide variety of habitats that amphibian surveyors may encounter in the region.

The book concludes with a complete Literature Cited section and list of General References. The list includes all the major national and regional publications of importance, plus some. One title that caught my attention was Petranka's (1997) *Salamanders of the United States and Canada* (Smithsonian Institution Press, Washington, D.C.). Unfortunately, it has not been published yet and may not be available until mid-1998.

The Pacific Northwest finds itself in excellent shape for amphibian monitoring with the publication of this book and the field guide of Corkran and Thoms (1996). The combination of the two books provides the needed methodologies along with excellent identification keys for all the species. Other regions of the United States and Canada should follow their lead. *Sampling Amphibians in Lentic Habitats* is a must-have book for anyone conducting field surveys of amphibians in the United States.

AARON M. BAUER
Department of Biology, Villanova University
800 Lancaster Avenue, Villanova, Pennsylvania 19085-1699, USA
e-mail: abauer@king_kong.vill.edu

This is a very different book from other recent treatments of geckos (e.g., Bartlett and Bartlett 1995; Henkel and Schmidt 1995; Seufer 1991), and one that has more general applicability outside of the realm of herpetoculturists. As the title implies, the book provides an overview of all living gekkotan genera, including a great many that are completely unknown to most amateur herpetologists and barely recognizable to even specialists.

The book opens with a review of gekkotan systematics and characteristics. Included are overviews of fossil geckos, body size and form, skin structure and function, sensory organs, sexual dimorphism, and locomotion (including the morphology of digital scansors). This section is well-illustrated by line drawings, scanning electron micrographs, and close-up color photos. Another introductory section deals with distribution and natural history and features maps illustrating subfamilial distributions (that for the Gekkoninae is incorrect but a replacement was provided on an errata sheet), an overview of activity period, social behavior, reproduction, and growth and longevity. Although the chapter heading suggests that the information is based on animals in the wild, many of the data presented have been supplemented by the author's own extensive observations on captive behavior, reproduction, and longevity. *Oedura* and *Phelsuma* are highlighted in particular.

The core of the book is a set of generic accounts, each providing brief physical characterizations of the lizards, natural history notes, a distribution statement, and literature citations. Most genera are illustrated by one or more color photos of representative species (the only taxa missing photos are the pygopods *Aclys*, *Ophidiocephalus*, and *Pletholax* and the gekkonines *Briba*, *Calodactylodes, Carinatogecko, Dravidogecko, Gymnodactylus*, *Luperosaurus*, and *Pseudogekko*). Most photos depict living specimens in captivity, but preserved museum specimens have been figured in some cases. Although not especially aesthetic, even these serve the purpose of giving the reader at least a sense of the appearance of a typical member of the genus. Photo quality varies considerably and many photos could have been improved by enlargement, judicious cropping, better depth of field, choice of a better background, or better lighting. Nonetheless, the vast majority are sharp and clear and provide "a face to go with the name." Only the photo of *Cnemaspis kandiana* is badly out-of-focus. A number of species are missidentified in the figure legends, the most glaring example being a photo of *Hemidactylus triedrus* labeled as *Cyrtodactylus tiredrus*. In fairness to the author, however, this and several lesser typos and misidentifications were noted on an errata sheet in my review copy. A few accounts are accompanied by representative habitat photos. More of these might have been a good thing, providing temperate zone gecko enthusiasts with a better sense of where the objects of their affection live.

In all, 96 genera are included in the work. The taxonomy employed is current for the publication date of the book, based primarily on the work of Kluge (1993), and including newly erected genera, such as *Saltuarius*. However, there have been several recent generic level revisions postdating Rösler's book: *Dravidogecko* has been sunk into *Hemidactylus* (Bauer and Russell 1995), *Phyllodactylus* has been broken into seven genera (Bauer et al. 1997), *Pseudothecadactylus* has been resurrected from the synonymy of *Rhacodactylus* (Good et al. 1997), *Millotisaurus* has been placed in the synonymy of *Lygodactylus* (Pasteur 1995), and Rösler's *Homopholis* is now referred to *Blaesodactylus*, and his *Platypholis* to *Homopholis* (Kluge and Nussbaum 1995). It is clear, however, that the author made every effort to accurately reflect the state of affairs in gecko systematics, praise that can be bestowed on precious few herpetocultural publications.

The generic accounts are followed by a 39-page chapter dealing with gecko husbandry. This provides basic information about terrarium construction, temperature, water, and food regimes, handling and transport of geckos, breeding, incubation, and disease and is based primarily on the author's own extensive personal experience with a wide variety of geckos in captivity. Unfortunately, the husbandry portion of the text largely excludes pygopods, resulting in a certain asymmetry in the completeness of the book as a whole.

Of special value in the husbandry section are three reference tables. The first provides a correspondence between gecko characteristics and behavior and the probable implications of these traits for keeping the animals (e.g., required substrates, environmental requirements, pairing or dominance problems). The second provides a brief physical description, recommended terrarium type, and comments for 78 species of geckos. The third table presents a wide variety of parameters of reproduction, egg dimension, incubation, and hatchling size for 49 species of geckos. The first of these tables will be especially useful for novice keepers, or those who may encounter an unknown, or incorrectly identified, gecko in the pet trade.

Finally, the text concludes with short sections on conservation status (especially as relating to geckos being kept in Germany), a list of gecko-focused organizations, and a brief glossary of 84 terms, most of which will be familiar to all but the most novice herpetologists. The literature cited section is extensive, with more than 1000 references, and current through approximately mid-1995 (many 1994 and 1995 references are included along with short synopses in an addendum). The literature citations contain some typos but are generally correct and include a wide array of papers dealing with systematics, natural history, and husbandry in a variety of languages (predominantly English and German). An index to scientific names and general topics is also included.

Although I noted a range of minor typos throughout the book, the text as a whole appears to be factually sound. The 41 genera with which I have had some field experience are generally accurately portrayed, although the brevity of accounts necessitates oversimplification in some cases. For example, *Ailuronyx seychellensis* is noted as occurring on palm trees. While this is true, I have also found them on banana plants, in abandoned houses, and in outhouses. For most readers, however, such minor quibbles will be irrelevant, and the text will provide a good first introduction to most gecko genera.

In its current form, in the original German, this book will be most useful to professionals and very serious amateur herpetologists. The fact that most genera are illustrated in color and that there is a comprehensive and up-to-date literature section make the book a handy guide to the living gekkotans. I can imagine that most herpetologists will find photos of genera they had never heard of and that the book will help both herpetoculturists and academic biologists gain some appreciation for the diversity of geckos. An English translation would be most welcome as it would make

Rösler's extensive breeding data for dozens of species more easily accessible to North American herpetoculturists who, as a group, lack experience with as broad a range of gekkotans as their European counterparts. *Geckos der Welt* is not perfect, but a more comprehensive illustrated guide to geckos and their biology has not been published. Accordingly, I recommend this book highly to anyone who wants or needs a single source of general information for gekkotan lizards.

PUBLICATIONS RECEIVED

A Classification of North American Biotic Communities, by David E. Brown, Frank Reichenbacher, and Susan E. Franson. 1998. The University of Utah Press, Salt Lake City. x + 142 pp. Softcover. US $19.95. ISBN 0-87480-562-7. Accompanying 42" x 42" map. US $20.00 [Book and map set, $34.95]. ISBN 0-87480-567-8.

This book outlines a uniform hierarchical classification of biotic communities north of the Panama Canal. The categories employed, from more to less inclusive are: biogeographic realm, hydrologic regime, formation-type, climatic zone, biotic community (regional formation), series (alliance of generic dominants), and association (plant community of specific taxa). The latter two categories are not dealt with comprehensively, but some examples are provided. A large number of the community types are illustrated in a series of 118 black and white photographs and all are indicated on the large accompanying map. The book also presents a detailed rationale for the system employed and an extensive bibliography. The classification scheme employed should provide a standard nomenclature for herpetologists and others involved in biotic inventorying or studies in ecological biogeography.

Aquatic Fauna in Peril: The Southeastern Perspective, edited by George W. Benz and David E. Collins. 1997. Special Publication 1, Southeast Aquatic Research Institute. Lenz Design & Communications, Decatur, Georgia. xviii + 554 pp. Hardcover. US $45.00. ISBN 0-9654841-0-6.

A proceedings volume based on a conference held in 1994 and sponsored by the Tennessee Aquarium. The book incorporates 17 chapters along with appendices (including state by state threatened and endangered lists) and subject, common name, and scientific name indices. Of herpetological interest are chapters by C. Kenneth Dodd, Jr. on "Imperiled amphibians: a historical perspective," Kurt A. Buhlmann and J. Whitfield Gibbons on "Imperiled aquatic reptiles of the southeastern United States: historical review and current conservation status," and Linda V. LaClaire on "Amphibians in peril: resource management in the southeast." The volume as a whole outlines the biogeography, ecology, conservation threats and status, and management of aquatic vertebrates and invertebrates throughout the southeastern United States and the text is supplemented by numerous maps, graphs, tables, and black and white and color photographs.

A Natural History of Australia, by Tim M. Berra. 1998. Academic Press, San Diego. x + 304 pp. Hardcover. US $44.95. ISBN 0-12-093155-9.

A Natural History of Australia presents one American's view of the geology and biology (including human) of the island continent. Although many plant and animal groups are dealt with, vertebrates receive the most attention. Amphibians and reptiles are dealt with in a 37-page chapter. As with other groups, the basic characteristics of families are outlined and selected taxa are illustrated by color photos or line drawings, and shaded range maps are provided. Summary information regarding snake bite and venom toxicity is also presented. Although the level of generality does not make this book suitable as a field guide, it is an excellent introduction to the Australian environment in general. In addition to the excellent graphics and entertaining prose, readers will find appendices on Australian slang and idiom and political, social, and demographic details particularly interesting. Bibliographic references and an index are supplemented by a listing of National Geographic articles dealing with Australia.

Early Notice for 1999 Annual Meeting

Although next year's annual SSAR meeting, to be held jointly with The Herpetologists' League and the American Society of Ichthyologists and Herpetologists at Penn State, seems like a long ways off (24–30 June 1999), the Call for Papers will be mailed much earlier than in years past—by 5 October 1998. The deadline for submission of abstracts is 15 December 1998. Further details are contained in the official Meeting Announcement and Call for Papers, to be mailed to all Canadian, Mexican, and U.S. members of SSAR. Overseas members wishing to receive this information may do so by contacting the Local Committee Chair, Jay Stauffer (e-mail: vc5@psu.edu; tel. 814/863-0645). A meeting web page is under development and may be accessed at: www.outreach.psu.edu/C&I/ASIH/.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, 35 Eighth Street, Frenchtown, New Jersey 08825, USA (tel. 908-996-4056 EST; e-mail: ejohnson@ptdprolog.net).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 640		$340
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$190

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@sluvca.slu.edu.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1998 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $30; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $24. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

1998 — University of Guelph, Guelph, Ontario, Canada, 16–22 July (James P. Bogart, Chair).
1999 — Pennsylvania State University, University Park, Pennsylvania, USA, 24–30 June (Jay Stauffer, Chair).

SSAR BUSINESS

HR Staff Changes

Lee Fitzgerald has stepped down as an Associate Editor for *HR*. In addition to this most recent role, Lee previously toiled as a Section Editor for Natural History Notes. On behalf of SSAR, the editors thank Lee for his efforts and contributions to colleagues.

Hal Avery (U.S. Geological Survey) and Sharyn Marks (Humboldt State University) have joined our staff as Associate Editors. E-mail addresses for each are provided on the inside front cover.

SSAR Grants-in-Herpetology

Proposals are now being accepted for the 1999 SSAR Grants-in-Herpetology Program. This program is intended to provide financial support for deserving individuals or organizations involved in herpetological research, education, or conservation. Grant proposals will be considered in the following categories:

1. CONSERVATION OF AMPHIBIANS AND/OR REPTILES. Proposals should address research (particularly conservation biology) on species endangered or threatened at the state, national, or international level, or address research on potentially threatened habitats or species, or on introduced injurious species. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

2. FIELD RESEARCH. Proposals may address needs for field station fees or equipment and materials in field oriented projects, or the field work portions of broader studies. This might include in-situ behavioral studies, ecological, life history, or sexual selection studies. Survey work by individuals or regional societies may be submitted here or in TRAVEL below depending on how the funds are to be used. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR, the president of the sponsoring regional society (if applicable), or a student's major advisor or committee chairperson.

3. LABORATORY RESEARCH. Proposals may address needs for equipment or materials in laboratory projects or laboratory portions of broader projects. This might include studies in behavior, biochemistry, molecular biology, biomechanics, or physiology. Proposals must be from individuals only and be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson.

4. HERPETOLOGICAL EDUCATION. Proposals may address an educational project or start up support for an educational program in a zoo, museum, park, nature center, regional herpetological society, etc. The project must focus on an herpetological topic. Proposals must be from individuals only and be accompanied by a letter of support from the herpetological curator, the director of the facility, or the regional society president.

5. TRAVEL. Proposals may address support for travel to field study sites near or far, or to utilize distant collections or facilities. If funding is sought to get from one place to another, proposals should be submitted in the TRAVEL category. Proposals normally submitted in the CONSERVATION or FIELD RESEARCH categories should be submitted here if travel funding is being sought. Proposals must be accompanied by a letter of support from another member of the SSAR or a student's major advisor or committee chairperson, or the regional society president.

6. INTERNATIONAL. Proposals may address needs in any of the above five categories, but applicants must be from countries where herpetological research has historically been underfunded, and where alternative sources of financial support are scarce or nonexistent.

In keeping with the Society's goal of encouraging participation by the broadest possible community, preference may be given to individuals who might not have access to other funding sources. All applicants must be members of the SSAR with the exception of those applying for support of regional herpetological society projects, or those applying in the international category. Membership dues must be paid (to SSAR Treasurer) no later than 31 December 1998 for proposals to be considered. Applicants are limited to submission of one proposal in one category per year. If proposals in any of the categories are not forthcoming, or judged not to be of sufficient quality, the funds in those categories may be transferred to other categories. Each proposal must include the following: (A) TITLE PAGE giving the title of the project, the name, mailing address, office and home telephone numbers and, if possible, fax number and e-mail address of the applicant. The title page should include a statement indicating that applicants "will comply with all applicable permit regulations, and adhere to all appropriate animal care guidelines in the course of conducting funded projects." (B) BACKGROUND AND OBJECTIVES of the proposed project. (C) METHODS of carrying out the project. (D) COMPLETE PROJECT BUDGET (regardless of whether the SSAR grant will entirely cover expenses). Include an explicit explanation of how an SSAR award of $500 would be applied toward the objectives of the project, and provide a current listing of all current and pending support for the project. (E) BRIEF RESUMÉ of the applicant or project coordinator. (F) LETTER OF SUPPORT. The proposal must be typed, double spaced, and must not exceed 1200 words, excluding title page, literature cited, resumé, and budget. Applicants must indicate word count on their application.

Applicants must designate to which of the six categories their proposal is submitted (although the committee reserves the right to reassign categories). All proposals must be submitted (postmarked) no later than 31 DECEMBER 1998 to be considered. Failure to meet these guidelines may result in elimination of a proposal from consideration. The awards will be announced on or around 1 April 1999. Successful applicants are encouraged to submit the results of their research for publication in the *Journal of Herpetology* or *Herpetological Review* or to present their findings at the annual meeting of the SSAR. Submit proposals or questions regarding application procedures to: *Joseph R. Mendelson III, Chair, SSAR Grants-in-Herpetology, Department of Biology, Utah State University, Logan, Utah 84322-5305, USA. Tel. (435) 797-2097; Fax (435) 797-1575; e-mail: sapo@biology.usu.edu.*

SSAR Henri Seibert Award for 1999

The Henri Seibert Award was initiated in 1992 to provide recognition for the best student papers given at the annual meeting of the SSAR. To be eligible, the presented paper must be the results of research conducted by the presenter, who must also be a current SSAR member. The research must have been done while the student was in either an undergraduate or graduate degree program. The presentations will be judged by the SSAR student prize committee. One Seibert Prize of US $200 may be given in each of the four categories: Conservation, Ecology/Evolution,

Physiology/Morphology, and Systematics. Please indicate the category to which you are submitting your abstract on the abstract form in the Call for Papers (to be mailed in early October 1998). Note also that past winners of this award are not eligible for participation in future Seibert Award competitions. Please refer to *Herpetological Review* 28(4):175 for recommendations to students entering next year's Henri Seibert competition.

Kennedy Student Award Committee Annual Report—1998

The Kennedy Award Committee has completed its work for Volume 31 of the *Journal of Herpetology*. The Committee has selected "The effects of reproductive mode and climate on reproductive success in the Australian lizard, *Lerista bougainvillii*" by Carl P. Qualls (Vol. 31[1]:60–65). As an undergraduate, Carl performed research under Bob Jaeger at The University of Southwestern Louisiana. The work reported in Volume 31 was a portion of his doctoral research under Rick Shine at the University of Sydney. Currently, he is a post-doctoral student in Robin Andrews' laboratory at Virginia Polytechnic Institute and State University, where is working with brown tree snakes in Guam.

Fifteen manuscripts were in competition this year. The Committee noted the high quality of the submitted papers. Committee members were: Robin Andrews (Virginia Polytechnic Institute & State University), David Duvall (Oklahoma State University), Robert E. Gatten, Jr. (University of North Carolina), Terry D. Schwaner (Southern Utah University), and Ken R. Marion (Chair, University of Alabama at Birmingham).

NEWSNOTES

David Wake Elected to U.S. National Academy

David B. Wake, long-time SSAR member and Gompertz Professor of Integrative Biology at the University of California at Berkeley, was recently elected to the U.S. National Academy of Sciences. He also serves as director of the Museum of Vertebrate Zoology. David is well known for a broad range of outstanding studies in evolutionary biology and is the leading authority on the systematics of plethodontid salamanders. In recent years, he has also investigated the neuroethology of salamander feeding mechanisms.

Election to the select membership of the National Academy is a singular honor for an American scientist and SSAR salutes David for this richly deserved tribute to his career as a research scientist.

North Texas Herpetological Society Scholarship Giving Reaches $10,000

Over the past six years the North Texas Herpetological Society has hosted its spring symposium. Its purpose is to provide education and further conservation efforts worldwide, particularly with regard to reptiles and amphibians. This is accomplished primarily with a day of speakers, an education room open to the general public, and through the dissemination of unrestricted scholarships

About Our Cover: *Siphlophis cervinus*

The similarity between the South American Emerald Treeboa, *Corallus caninus*, and the Indo-Australian Green Tree Python, *Morelia viridis*, is famous. But many other reptiles, separated by huge phylogenetic and geographic distances, share motifs of color and pattern, often resembling one another to an astonishing degree. Among the snakes, the harlequin decorations involving black-and-cream rings, spots, or bands coupled with a brilliant red or orange mid-dorsal stripe are particularly striking. Such a pattern can be seen, for example, in the South African *Homoroselaps lacteus*, in the Central American *Scolecophis atrocinctus*, and in the South American *Oxyrhopus leucomelas*.

It also appears in an odd little snake called *Siphlophis cervinus*. The Neotropical genus *Siphlophis* includes five species: *S. cervinus*, *S. leucocephalus*, *S. longicaudatus*, *S. pulcher*, and *S. worontzowi* (Peters and Donoso-Barros 1970. Catalogue of the Neotropical Squamata. Part 1. Snakes. Washington, DC, 347 pp.). Four of these species are Brazilian endemics (Peters and Donoso-Barros 1970, *op. cit.*), a bizarre Panamanian reference for *S. longicaudatus* notwithstanding (Villa, Wilson, and Johnston 1988. Middle American Herpetology. A Bibliographic Checklist. Columbia, Missouri, 131 pp.). The Liana Snake, *Siphlophis cervinus*, ranges from Panama and Trinidad south to Bolivia and tropical Brazil. It is a denizen of rainforests, where it leads a mostly arboreal life. Under cover of darkness, it forages actively in shrubs and trees for lizards, and has been known to consume *Anolis* and *Tropidurus*. Juvenile Liana Snakes, which hatch from eggs, resemble adults in color and pattern.

Why would a snake, especially a nocturnal one, possess such a startling combination of colors? And why would species dissimilar in habits and habitats look so much alike? We know something about sight in vertebrates, but next to nothing about vision, the complex interaction of the brain's processing of optic nerve information and how this is presented to the consciousness (Walls 1942. The Vertebrate Eye. Bull. 19. Cranbrook Inst. Science, 785 pp.). When we can simulate the way other creatures see, it will be instructive to take a walk in the woods....to look at things through the eyes of a civet or an owl, or some other predator. Surely many peculiarities of the animal world, especially those involving color and pattern, will begin to resolve themselves.

The cover photo depicts an adult male *Siphlophis cervinus* approximately 750 mm long. The sleeping snake was photographed by **William W. Lamar** during late afternoon, as it lay coiled among vegetation in Amazonian rainforest along the Pindoyacu River, Loreto, Peru. Lamar made the shot on a tripod with an aged Pentax LX 35mm camera and a Vivitar Series 1, 105mm macro lens. The image was captured under natural light at f27 on Fujichrome Velvia film.

Commenting on his photo technique, Bill said, "I have minimal equipment, and all of it is old and badly worn. I like a variety of approaches, at various focal lengths, using both fill-flash and natural light, and very slow film. I know the look I want to capture: intimate, immediate, and natural. The problem is, I lack the skills to get what I want. But the trying is worthwhile!"

Bill Lamar is Adjunct Professor in the School of Sciences at The University of Texas at Tyler, and a Research Associate at The University of Texas at Arlington Collection of Vertebrates and the Natural History Museum of The University of Kansas. He has lived or worked in Latin America for over twenty years and is well-known for his scientific and popular publications. Excerpts from his memoir, *Primitive at Heart*, can be found in editions of *Fauna* magazine. He recently authored *The World's Most Spectacular Amphibians & Reptiles* (World Publications), now in its third printing. Lamar spends much of his time in the tropics of Latin America, where he works with documentary film makers and conducts natural history tours for GreenTracks, Inc.

Separation and imaging of Lamar's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

to deserving graduate students in the fields of herpetology, wildlife science, and conservation ecology.

The NTHS is proud to announce that, as of this year, a total of $10,000 has been awarded to graduate students from five different universities. The annual symposium is generally held in April. Interested individuals wishing to be put on next year's notification list should contact the Scholarship Chairman, K.C. Rudy (animan@flash.net) or write the NTHS at P.O. Box 1043, Euless, Texas 76039, USA.

Charles Stearns Grant-in-Aid for Herpetological Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one page—description of the research project, a budget, and a letter of support from the student's faculty advisor.

Proposals are due on 15 October 1998, with notification by 1 December 1998. Grantees are expected to complete their Academy visit by 15 September 1999. Please call 415-750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

Brett Stearns Award for Chelonian Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round-trip transportation and limited per diem expenses—to researchers who wish to visit our collections to support their work in chelonian biology. Preference will be given to graduate students.

Proposals should include a short (e.g., one page) description of the research project and a budget. In the case of graduate students, a letter of support from the student's faculty advisor is required.

Proposals are due on 15 October 1998; notification will be made by 1 December 1998. Awardees are expected to complete their Academy visit by 15 September 1999. Please call (415) 750-7039 for further information.

Proposals should be sent to: *Chelonian Research Awards, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

The CAS chelonian holdings are included in the Department of Herpetology database: www. calacademy.org.

MEETINGS

Meetings Calendar

1–5 October 1998—3rd Annual Meeting of the Canadian Amphibian and Reptile Conservation Network in conjunction with the 8th Annual Meeting of the IUCN/SSC Task Force on Declining Amphibian Populations in Canada (DAPCAN), University of Saskatchewan, Saskatoon, Saskatchewan, Canada. Contact: Andrew Didiuk, Local Organizer; e-mail: Andrew.Didiuk@ec.gc.ca; tel: 306-975-4087; fax: 306-975-4089.

2–6 March 1999—19th International Symposium on Sea Turtle Biology and Conservation, South Padre Island, Texas, USA. *(Refer to detailed information below).*

13–17 May 1999—Fourth International Symposium on Isolated Vertebrate Communities in the Tropics, Bonn, Germany. Hosted by the Zoologisches Forschungsinstitut und Museum Alexander Koenig. To receive announcements and to obtain further information, please contact: Prof. Dr. W. Böhme, Adenauerallee 160, 53113 Bonn, Germany; tel. +49 228 91 22 250, fax ++49 228 216 979, e-mail: r.hutterer.zfmk@uni-bonn.de.

8–11 October 1999—Second Symposium on the Status and Conservation of Florida Turtles, Eckerd College, St. Petersburg, Florida, USA. Contact: Gopher Tortoise Council, c/o George L. Heinrich, 1223 Alhambra Way S., St. Petersburg, Florida 33705-4620, USA; tel. (813) 865-6255; e-mail: highpine@gte.net.

19th International Sea Turtle Symposium

The 19th International Symposium on Sea Turtle Biology and Conservation will be held at South Padre Island, Texas, USA from 2–6 March 1999. This will be the last symposium of the millennium. We have chosen a primary historical theme for the meeting entitled, "The Promise, the Pain, and the Progress of 50 years of Sea Turtle Research and Conservation."

The symposium meeting site will be the South Padre Island Convention Center which is located adjacent to a salt marsh on Laguna Madre. The primary lodging site, "Bahia Mar Resort," which has many lodging options including condominiums of various sizes, is located within walking distance across the narrow island on a wide Gulf of Mexico beach. Excellent rates for rooms, food, air fares, and ground transportation have been negotiated with local vendors who have agreed to provide a 10% return to the Symposium. Southwest Airlines and Advantage Rental Cars have also agreed to give us special rates.

Registration will begin on Tuesday afternoon (2nd March) followed by an evening social at the Convention Center. Friday evening is set aside for the banquet and dance. The last official activity will be the IUCN Marine Turtle Specialist Group meeting on Saturday morning (6th March). If you have not previously attended a turtle symposium and are therefore not included in the symposium mailing list, then please contact Jane Provancha, Symposium Secretary, Aquatics Ecological Program, DYN-2, Kennedy Space Center, Florida 32899, USA; e-mail: Jane.Provancha-1@ksc.nasa.gov; Fax: (407) 853-2939.

Travel funds are available to assist international participants in their efforts to attend the Symposium in Padre Island. Awards should not be expected to cover the full cost of travel. Priority will be given to those who will be presenting papers or posters, those who apply before the deadline, and to individuals from relatively under-represented regions. If you are in need of assistance for travel to the Symposium, contact the relevant regional committee representatives before 1 December 1998. A copy of your abstract should accompany your application if you will be presenting a paper or poster. Candidates should have no hesitation in contacting their regional chair for letters of invitation or advice.

Americas/Caribbean: Wallace J. Nichols, University of Arizona-Wildlife Ecology, Fax: (650) 651-1579; e-mail: jnichols@ag.arizona.edu.

Asia and Pacific: Marydele Donnelly, IUCN, MTSG, Fax: (202) 872-0619; e-mail: mdonnelly@cenmarine.com.

Africa and Europe: Brendan Godley and Annette Broderick, Marine Turtle Research Group, University of Glasgow, Fax: + 44 141 330 5971; e-mail: MTN@bio.gla.ac.uk.

A limited number of travel awards will be made available to students travelling from within the USA. Candidates should contact Travel Committee Chair, Wallace J. Nichols (above).

Symposium on the Status and Conservation of Florida Turtles

A Second Symposium on the Status and Conservation of Florida Turtles will be held at Eckerd College in St. Petersburg, Florida on 8–11 October 1999. Co-sponsored by Eckerd College, the Gopher Tortoise Council, and the Florida Turtle Conservation Trust, this symposium will address the problems faced by Florida turtle species, as well as conservation strategies and specific recovery solutions.

Paper session topics include populations, habitat, disease, commercial trade, and conservation measures. In addition to a poster session and field trips, workshops on the identification of emydid turtles, field methods, and environmental education are scheduled.

A volume describing the conservation biology of Florida turtles at the end of the 20th century is planned. We anticipate that it will include 25, mostly multi-authored, accounts. Anyone wishing to contribute to one or more species accounts is asked to contact Peter Meylan (e-mail: meylanpa@eckerd.edu).

For more information about the symposium, contact the Gopher Tortoise Council, c/o George L. Heinrich, 1223 Alhambra Way S., St. Petersburg, Florida 33705-4620, USA; tel. (813) 865-6255; e-mail: highpine@gte.net.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Anne Maglia or Christopher Sheil; postal and e-mail addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are listed. The Web site address is:

http://www.sisna.com/users/Herpbooks/Contents.html

Molecular Phylogeny and Biogeography of Elapid Snakes

Keogh sequenced regions of the 16S rRNA and cytochrome *b* mitochondrial DNA genes from 17 species (distributed among 16 genera) of elapid snakes. These data were analyzed separately, as well as combined as a single data set. Results of his analyses support several hypotheses (e.g., American and Asian coral snakes are a natural [monophyletic] group; true sea snakes do not form a monophyletic group, but rather have arisen several times from terrestrial Australo-Papuan elapids). Keogh suggests an African, Asian, or Afro-Asian origin of elapid snakes, and an independent Asian origin of American (micrurine) coral snakes (dispersal via land bridges) and the hydrophiines. This study discusses the possible Gondwanan and Laurasian origin of the Elapidae.

KEOGH, J. S. 1998. Molecular phylogeny of elapid snakes and a consideration of their biogeographic history. Biol. J. Linn. Soc. 63:177–203.

Correspondence to: J. Scott Keogh, Division of Botany and Zoology, Australian National University, Canberra, ACT 0200, Australia.

Varanid Biogeography

The authors sequenced regions of the 12S rRNA gene from 21 extant species of *Varanus*. Results of their study indicate that the Australian varanids form a monophyletic group, and that the pygmy monitors (subgenus *Odatria*) may form a monophyletic clade with respect to the large monitors (subgenus *Varanus*). Their results support an Asian origin of Australian varanids. Asian varanids were found to be more closely related to the Australian taxa than were the African varanids, possibly suggesting a non-Gondwanan origin of Varanidae. Both parametric and nonparametric statistics were employed to test hypotheses of relationships based on their 12S data, which were constrained according to previously described topologies based on hemipenial, lung, and chromosomal morphology.

Invasion Ecology of *Bufo marinus*

The investigators employed mark-recapture studies in Australia and South America to demonstrate that *Bufo marinus* achieves much higher densities in Australia (where they are an introduced species) than in their native habitats in South America. From the population model presented in their study, predictions of adult equilibrium densities and tadpole survival rates at equilibrium are consistent with what they reported in South America and Australia. Also, the mean basic reproductive number estimated for these two continents is greater than 1, which confirms the invasion and reproductive potential of this toad. Only postmetamorphic survivals contribute to adult equilibrium densities and it was determined that adult equilibrium densities are increasingly sensitive to incremental change in adult survival. Basically, higher adult survival in Australia likely explains the higher densities of this species on that continent. Survival estimates also were found to be in favor of Australian *B. marinus* over their South American counterparts (nearly 3:1). The major ecological factors contributing to the greater densities of this toad in Australia, as compared to South America, are unkown.

LAMPO, M., AND G. A. DE LEO. 1998. The invasion ecology of the toad *Bufo marinus*: from South America to Australia. Ecol. Appl. 8(2):388–396.

Morphology of *Dibamus taylori* and Relationship of Dibamidae within Squamata

Jakob Hallerman describes, in great detail, the nasal capsule and nasal sac of *Dibamus taylori,* employing techniques of serial sectioning. The morphology of *D. taylori* is compared with representatives of several other lizard genera, and a discussion of the similarities and affinities between *Dibamus* and Scincomorpha, amphisbaenians, and snakes is included as well. Cartilaginous and epithelial characters, as well as characters from other regions of the body, are employed in a phylogenetic analysis, indicating the following relationships (((Dibamidae, Amphisbaenia) Serpentes) Scleroglossa).

HALLERMANN, J. 1998. The ethmoidal region of *Dibamus taylori* (Squamata: Dibamidae), with a phylogentic hypothesis on dibamid relationships within Squamata. Zool. J. Linn. Soc. 122:385–426.

Correspondence to: Jakob Hallermann, Zoologisches Institut und Zoologisches Museum der Universität, Martin-Luther-King-Platz 3, D-20146 Hamburg, Germany; e-mail: fb6a044@rrz-cip-1.rrz.uni-hamburg.de.

Integrative Approach to the Study of Pheromones

In this paper, Houck discusses the emergence of the use of integrative methodology in amphibian research. She focuses her review on studies of physiological changes associated with behavioral performances, specifically those relating to reproductive pheromones. Integrated approaches are used most often in two types of studies within the field of pheromonal research: 1) those examining pheromonal influences on behaviors directly linked with courtship success; and 2) field studies of the hormonal basis of reproductive behavior. She provides an excellent overview of most of the recent works on salamander reproductive pheromones and behavior, and shows how seemingly disparate works (e.g., studies on neural pathways, behavior, chemical composition of pheromones, and phylogenetic relationships) all combine to give a greater understanding of the role of pheromones in reproductive behavior.

Synchronous Emergence as an Antipredator Mechanism

The authors tested the hypothesis that synchronous metamorphosis in *Bufo boreas* acts as a mechanism against predation by garter snakes (*Thamnophis*). In laboratory experiments, they measured the time to emergence from water, the number of metamorphs emerging together, and level of aggregation of toads with and without the presence of garter snakes. They found that in the presence of a predator, toads will emerge sooner, will aggregate more, and more toads will emerge in synchrony. Although toads emerged synchronously, many individuals were not at the ideal developmental stage for terrestrial movement. Therefore, the authors suggest that variability in emergence time may be a flexible response to multiple selection pressures caused by the presence of a predator.

DEVITO, J., D. P. CHIVERS, J. M. KIESECKER, A. MARCO, E. L. WILDY, AND A. R. BLAUSTEIN. 1998. The effects of snake predation on metamorphosis of western toads *Bufo boreas* (Amphibia, Bufonidae). Ethology 104:185–193.

Correspondence to: J. Devito, Department of Biology, Angelo State University, San Antonio, Texas 76909, USA; e-mail: jill.devito@angelo.edu.

Multiple Paternity in *Rana temporaria*

By collecting newly-laid egg masses, raising the larvae, and examining allozyme frequencies of individuals from each clutch, the authors examined the occurrence of multiple paternity and sperm competition in *Rana temporaria.* They found lower than expected (from single mating) levels of average relatedness. They suggest that egg clutches of these frogs often contain individuals sired from different males and that communal breeding effects paternity patterns in these and other frogs.

Sexual Condition, Diet, and Temperature in Desert Lizards

To determine the effects of sexual condition on food consumption and body temperature selection in the herbivorous desert lizard, *Uromastyx philbyi,* the author conducted laboratory experiments on male and gravid and non-gravid females. Lizards were fed *ad libitum* and the amount of food consumed by each over a 21-day period was measured. To determine temperature selection, lizards were subjected to thermogradients and their body temperatures were measured for a 24-h period. Zari found that both sexes had significantly higher body temperatures during daytime conditions than at night. Gravid females had the lowest food consumption rate, chose the highest body temperatures, and remained at these selected temperatures for a longer period of time. The author suggests that this probably allows for more rapid egg development. Also, the reduced energy intake of this species (relative to others) is most likely an adaptation to life in a hot desert environment.

ZARI, T. A. 1998. Effects of sexual condition on the food consumption and temperature selection in the herbivorous desert lizard, *Uromastyx philbyi.* J. Arid Envir. 38:371–377.

Correspondence to: T. Zari, Department of Biological Sciences, Faculty of Science, King Abdul Aziz University, P.O. Box 9028, Jeddah 21413, Saudi Arabia.

Relationships and Evolution of the *Bufo bufo* Species Group

In this study, the authors investigate the phylogenetic relationships of frogs in the *Bufo bufo* species group using mitochondrial DNA sequences. They test the two major hypotheses for the colonization of the Tibetan Plateau: 1) vicariant speciation by uplifting of the Plateau, in which case populations at high elevations should be monophyletic, and 2) dispersal after the uplift, in which case high elevation and low elevation populations should be closely related. The single most parsimonious tree resulting from their analysis suggests that species in the *Bufo bufo* group form a monophyletic assemblage and that within the group, the Asian species (also a monophyletic assemblage) form two major clades. Their hypothesized groupings support neither the vicariant nor the dispersal hypothesis for colonization of the Tibetan Plateau. Instead, they suggest that a combination of vicariance and subsequent dispersal is responsible for the current distribution of *Bufo* in this area.

MACEY, J. R., J. A. SCHULTE, A. A. LARSON, Y. WANG, B. S., TUNIYEV, AND T. J. PAPENFUSS. 1998. Phylogenetic relationships of toads in the *Bufo bufo* species group from the eastern escarpment of the Tibetan Plateau: A case of vicariance and dispersal. Mol. Phylog. Evol. 9:80–87.

LETTERS TO THE EDITOR

Morphology and the Status of the Snake Genus *"Ptyas"*

JAMES LAZELL
The Conservation Agency
6 Swinburne Street, Jamestown, Rhode Island 02835, USA
e-mail: jcinjtown@aol.com

Three species of Asian racers bearing a close and detailed resemblance to the North American *Coluber constrictor*, type species of the genus *Coluber*, have often been separated from other racers as the genus *Ptyas*. I reiterated the history of the putative genus *Ptyas* and discussed the one morphological character then said to distinguish *Ptyas* from *Coluber*: relative tooth size (Lazell et al. 1991). Variation within and among the species in question—American *constrictor*, mainland Asian *mucosus* and *korros*, and Sulawesi *dipsas*—is broadly overlapping and not even the extremes are distinctive in tooth size. Therefore, Lazell et al. (1991) formally synonymized "*Ptyas*" under *Coluber*. The purpose of this note is to correct apparent errors which have led to continued use of the name "*Ptyas*."

Zhao and Adler (1993) separated *Coluber* from *Ptyas* at the generic level in their key couplet 26 (p. 88): "Top of head normally with nine large, symmetric shields" leading to *Coluber* and "Top of head not as in 26A" leading to *Ptyas*. The clear implication is that *Ptyas* does not have the common colubrid arrangement of head shields and is distinct in this respect from *Coluber*. This is erroneous. Two errors have been compounded. First, Pope (1935) mistakenly believed *Coluber* had a single loreal and *Ptyas* had two loreals. The number of loreals is variable in *Coluber* sensu lato and has not been used as a generic character since Pope (1935).

Second, loreals are not among the "nine, large symmetric shields" on the top of the head in *Coluber*. The head shields of all three Asian species number nine and are identical in configuration to those of *Coluber constrictor* (Lazell et al. 1991, Fig. 1 for *Coluber dipsas*). There is no morphological basis for recognition of a genus "*Ptyas*" as separate from *Coluber* sensu stricto.

Acknowledgments.—I am indebted to K. Adler (in litt. 15 January 1997) and E. Zhao (in litt. 2 May 1997) for explaining the sources of these two errors. V. Wallach assisted me in checking head scales at the Museum of Comparative Zoology.

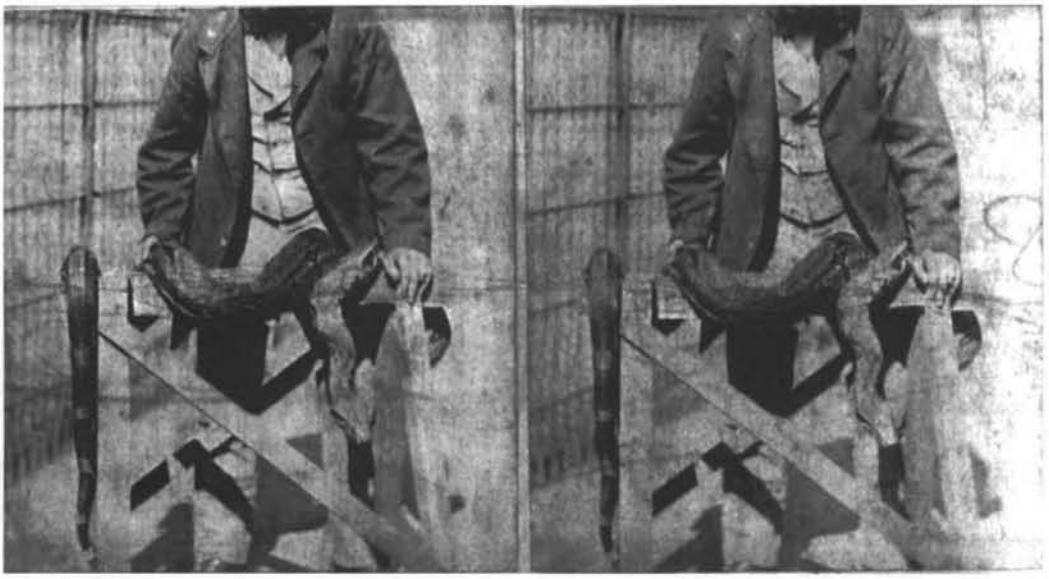
Early Reptile Photography

JOHN EDWARDS
26, Rhondda Grove
London E3 5AP, England

I enclose a transparency of a photograph of an unknown keeper at London Zoo holding a *Boa constrictor* (Fig. 1). The original is actually a Magic Lantern Slide about 3.25 inches square. The photograph has been developed onto glass in order that it can be projected onto a screen, just as modern colour transparencies are projected.

FIG. 1. Keeper with Boa Constrictor. Photographed from life by Frank Haes, 1865.



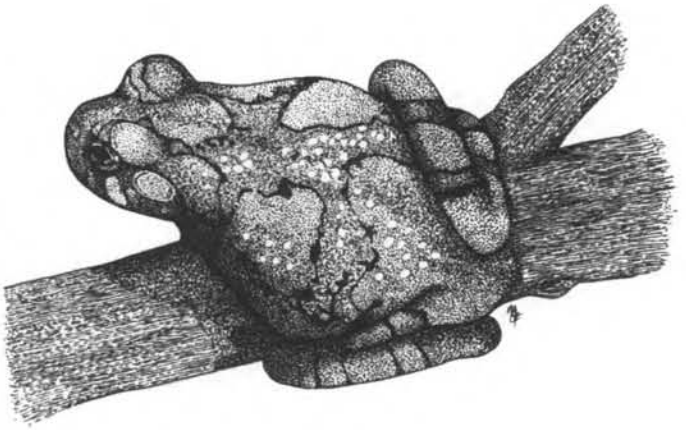


FIG. 2. The Boa Constrictor. Photographed from life by Frank Haes, 1865. This is an example of the stereoscopic card method of publication typical of the period.

Magic Lantern Slides by this photographer, Frank Haes (1832–1916), are extremely rare and indeed, the only ones I know of are in my own collection. Most of his London Zoo photographs were published in the form of stereoscopic cards—that is, two slightly different photographs (the view as seen from each eye) were mounted side by side and when looked at through a viewer a three-dimensional view is obtained (Fig. 2). This was particularly desirable when an animal was photographed from behind bars. Haes took photographs at the London Zoo in the summer of 1864 and amongst the images known to have been secured, was one of a tortoise and another of a Tasmanian or Thylacine Wolf, neither of which I have seen. This tortoise was the only reptile in the 1864 series and may thus be the earliest photograph ever taken of a reptile. Certainly it is the oldest known to me. Haes wrote about his 1865 season at the Zoo in *The Photographic News* for 23 February 1866. On page 91, he wrote:

> 'The Boa Constrictor, of which you have before four portraits, was not in good health at the time; it is since dead. It measured about thirteen feet in length, and in the thickest part girthed nearly eighteen inches. The yellow snake of Jamaica was an active fellow, and looks in the photograph spiteful enough.'

I recently acquired a rather battered stereoscopic card of a Boa Constrictor by Haes (Fig. 2). It is impossible to say which of the photographs is earlier—they may have been taken within minutes of each other. Haes also photographed 'Yellow Snake of Jamaica' (I am not sure what this might have been—probably the Yellow Tree Boa *Epicrates inornatus* [Reinhardt] which was first received at London Zoo in 1851 and which bred on several occasions between 1851 and 1873. Thus the photographs which I possess are the earliest which I have seen personally, although I know that other have existed and may, I hope, still exist.

The snakes were photographed around their keepers' necks, or draped over trestles because the glass fronts of their cases reflected the light. For this reason, I think that venomous snakes were not photographed! It is a curious fact that the Count of Montizon, who photographed a living pike (believed to be the first photograph ever taken of a living fish), never seems to have attempted a reptile. One would have thought that a tortoise would have been easier than a fish. In this connection, I have always thought that at least part of Montizon's reasons for taking animal photographs was to demonstrate his skills as a photographer, rather than an interest in zoology. Many early photographs of animals which purport to be of living specimens are actually of museum specimens.

Hyla chrysoscelis, by Michael G. Frick

INSTITUTIONAL PROFILE

Department of Herpetology, Zoological Institute, Russian Academy of Sciences, St. Petersburg, Russia: History and Current Research

NATALIA B. ANANJEVA
Curator of Herpetology
Head of the Laboratory of Herpetology and Ornithology
Zoological Institute, Academy of Sciences, 199034 St. Petersburg, Russia
e-mail: nbanorus@glasnet.ru

Early History

The origins of herpetology in St. Petersburg can be traced to the time of Peter the Great when the first museum in Russia—called the Cabinet of Curiosities, or Kunstcamera—was founded in this capital of the Russian Empire. In 1717, Peter the Great personally purchased for the Kunstcamera the famous collection of Albertus Seba, a wealthy merchant and amateur naturalist in Amsterdam, including 120 amphibians and reptiles (the first Seba collection) which became the original specimens of our herpetological collection (Juriev 1981). The Academy of Sciences was founded in 1724 and the Kunstcamera (together with its associated library) became its responsibility. This period was a time of exploration and description in herpetology. Many new collections were obtained by the first expeditions of the Academy of Sciences and by purchases abroad (including part of the second Seba collection, purchased at auction in 1752). Among the first expeditions of interest to herpetologists was Peter S. Pallas's trip in 1768–1773 in eastern Russia and Siberia. Herpetological studies can be traced to Pallas and the historical center of Russian herpetology was the Zoological Museum (now Institute) in St. Petersburg. One result of Pallas's great expedition was that a number of new amphibians and reptiles were described. Most of the collections (including amphibians and reptiles) were taken to the Crimea where he finished writing his classic book, "Zoographia Rosso-Asiatica" (Svetovidov, 1978). Unfortunately, most of his material is no longer available; some specimens later were transferred to the Zoologisches Museum der Humboldt-University in Berlin and the Museum National d'Histoire Naturelle in Paris.

The further development of herpetological research is associated with the official recognition of the Zoological Museum as an independent Institution in 1832, whereas previously it was only a part of the Kunstcamera. The first museum director, Johann F. Brandt, was well known for his herpetological activity; he described some new species of Asian reptiles and enlarged the collection (from various expeditions within the Russian Empire and abroad, particularly from Baron Georg Heinrich von Langsdorff in Brazil; and through exchanges with other museums). Brandt and Alexander A. Strauch, who replaced him in the post of the museum director, both of whom were academicians, were founders of the Russian school of herpetology.

Strauch is an especially important figure in the history of Russian and, indeed, world herpetology (Scarlato 1982; Adler 1989). He had serious scientific communication with most of the leading herpetologists of the day and used these contacts to increase the herpetological collection through purchase and exchange with other museums. A very significant source of new and interesting materials was from the first expedition of the famous explorer Nikolai M. Przewalski in the vast unknown regions of Central Asia. By 1882, the herpetological collection included 5889 catalogue numbers representing 1222 species of reptiles (119 species of turtles, 14 crocodiles, 596 lizards, and 493 snakes) and 1285 catalogue numbers of 283 species of amphibians (9 caecilians, 224 frogs, and 50 salamanders), i.e., it was widely representative for its time (Strauch 1889). As a result of his own careful study of these, Strauch wrote several monographs and world synopses of turtles, crocodiles, lizards, snakes, and salamanders (Strauch 1866, 1869, 1870, 1873, 1887, 1890). His review of the snake fauna of the Russian Empire (1873) and results of his identification and description of the amphibians and reptiles (1876) from Przewalski's first expedition to Central Asia are of special value for Russian and world herpetology.

The Department of Herpetology was officially recognized as a separate administrative unit only in 1915 and until that time it was part of a combined division of fishes, amphibians, and reptiles in the Zoological Museum. The curator of this combined division during the period 1896–1903 was the widely known herpetologist Alexander M. Nikolsky (Mazurmovich 1983; Adler 1989). Nikolsky was the author of several important monographs, including synopses of the herpetofaunas of Turkestan (1899) and the Caucasus (1913), and the first comprehensive books on our amphibians and reptiles ("Fauna of Russia and Adjacent Countries," in three volumes, 1915, 1916, 1918). Another important contribution of Nikolsky was the study, identification, and description of the rich herpetological materials collected in Iran by N. A. Zarudny, who was one of the first zoologists to study the diverse fauna of Persia. Nikolsky's contemporary, the well-known herpetologist Jacques von Bedriaga, was informally associated with the Zoological Museum. His most famous and important contribution was a large monograph (in quarto and nearly 800 pages; 1898–1912) devoted to the study of the huge herpetological collections made by Przewalski and other Russian explorers during their Central Asian expeditions (Adler 1989; Bogdanov 1891; Zhao and Adler 1993).

FIG. 1. Main buildings of the Russian Academy of Sciences, Saint Petersburg, along the north bank of the Neva River, opposite the Hermitage (December 1986). From left, the buildings house the Academy Administration, Anthropology Museum, and Zoological Institute (where herpetology is located on the top floor at the far right of the complex). The gold spire of the Fortress of Peter and Paul, where Russian czars are buried, is at the far right.

Modern History

Sergius F. Tsarevsky was curator of the newly independent Department of Herpetology during 1915–1929; he published important works on the taxonomically complicated groups *Eryx* and *Phrynocephalus*. After the museum's name was changed to the Zoological Institute in 1930, Sergius A. Chernov, a student of Nikolsky, was appointed curator of the Department of Herpetology, succeeding Tsarevsky. Chernov, who became the leading Soviet herpetologist during his curatorship (1930–1961), conducted extensive herpetological field work in the Transcaspian region (1932), the Caucasus (1937–1939), and in Tajikistan (1942–1944). The results were published as a series of articles and several monographs including regional synopsis of herpetofauna of Armenia (1937, 1939) and Tajikistan (1959). His most widely-known work was a book, "Field Guide to the Reptiles and Amphibians of the USSR," coauthored with Paul V. Terentjev (three editions in 1936, 1940, 1949), that was translated into English in 1965. During the last years of his life, Chernov studied the taxonomy of Palearctic snakes, focussing on peculiarities of the skull (Adler 1989).

Paul Terentjev, a prominent herpetologist and author of the world's first textbook of herpetology, worked in the Department of Herpetology during World War II including the German siege of Leningrad (1941–1944). He studied taxonomy and biogeography, mostly of the Anura, but also conducted ecological, biometric, and evolutionary research (Adler 1989; Scarlato 1982).

In 1962, Ilya S. Darevsky, a former student of Chernov, was appointed curator of the Department of Herpetology and, later, head of the Laboratory of Ornithology and Herpetology from 1976 to 1996. His research interests are associated with taxonomy, morphology, natural history, biogeography, and speciation in reptiles. Much of his research is devoted to the phenomenon of natural parthenogenesis and polyploidy in higher vertebrates, discovered by him in 1957 in a polymorphic group of Caucasian rock lizards related to *Lacerta saxicola* (Darevsky 1967; English translation, 1978). This important discovery has stimulated similar research and made Darevsky a leader of the new branch of science that concentrates on the study of the hybridogenous origin and speciation of clonal species of reptiles. It was developed successfully by Darevsky and his department colleagues (Larissa Kupriyanova, Felix Danielyan), and partly in collaboration with herpetologists from the USA (Thomas Uzzell), Canada (Robert W. Murphy), and Austria (Josef Eiselt).

Beginning in 1996, the curatorship of the Department of Herpetology and administration of the Laboratory of Ornithology and Herpetology passed to Natalia B. Ananjeva. Today, the herpetology staff consists of nine persons: five research workers (Natalia Ananjeva, Leo Borkin, Ilya Darevsky, Larissa Kupriyanova, Nikolai Orlov), two collections managers (Larissa Johanssen, Konstantin Milto), one technical assistant (Julia Smirnova), and a Ph.D. student (Igor Danilov). As of 1997, we also have a Ph.D. student (Spartak Litvinchuk) and a Ms.D. student (Svetlana Kalyabina) who are preparing their dissertations in our department.

Herpetologists of the Zoological Institute traditionally conduct research associated with the problems of biodiversity of amphibians and reptiles of Russia and adjacent countries, their taxonomy, ecology, phylogeny, and biogeography, continuing the traditions established in the last century. The most important results during the last two decades have been taxonomic revisions of rock lizards (Darevsky), agamid lizards (Ananjeva), viperid snakes (Orlov), and brown frogs (Borkin) of Palaearctic Asia, using a number of approaches and methods including biochemical and cytological analysis (Proceedings of the Zoological Institute of the USSR Academy of Sciences, 1977, 1979, 1981a, 1981b, 1984, 1986, 1987, 1990). These workers personally led more than 50 expeditions which include field studies in all regions of the former USSR.

Current Research

Traditionally, research interests focus mainly on Asia. One of the most intensively explored regions—from Nikolsky's day to the present—is the Caucasus. Despite intensive studies over long periods by many herpetologists, even during the last two decades a lot of new distributional data on amphibians and reptiles was obtained and many new species and subspecies were described from the territory of the Caucasus. The study of the herpetofauna of Armenia and adjacent areas of Turkey and Iran also continues. Significant herpetological research has been done during the last three decades in Middle Asia and Kazakhstan. As a result, several taxonomic revisions and descriptions of new forms were published by research workers and students in our department. Important work by Boris Tuniyev, a postdoctoral fellow, was based on the results of joint work with our staff and was devoted to the analysis of the origins of the herpetofauna of the mountain systems of Alpine Folding (Orogenesis) in the Caucasus and Central Asia (1995).

New data were also obtained in eastern Siberia, the Far East, and the European part of Russia. This information was published in a number of papers in Russian, German, and English and shortly will be summarized in a new edition (Ananjeva, Borkin, Darevsky, and Orlov 1998) of a synopsis of the amphibians and reptiles of Russia and adjacent territories (the former USSR).

The department's Asiatic herpetological research is not limited by the geographical boundaries of the former USSR. Extensive field work has been done in Mongolia (Ananjeva, Borkin, Orlov) within the framework of the joint Soviet-Mongolian Biological

FIG. 2. Staff of the Department of Herpetology, including doctoral students (November 1957). Left to right (seated): Sergei A. Chernov (curator), Paul V. Terentjev (professor at Leningrad University), Lev I. Khosatzky (docent at Leningrad University); (standing): Kirill B. Yuriev (Ph.D. student), Ilya S. Darevsky (postdoctoral fellow), Ludmila N. Lebedinskaya (collection manager), Günther Peters (Ph.D. student from Berlin), Abdulla M. Alekperov (Ph.D. student from Baku).

Expedition in 1981–1988 which led to important results on the distribution, natural history, ecology, and taxonomy of amphibians and reptiles that are published in a number of papers and monographs on amphibians (1988) and reptiles (1998). Through collaborations with herpetologists from various institutions in Moscow (Sergius Kuzmin, Valentina Orlova, Dmitri Semenov) and Mongolian colleagues (Khorlooghiyn Munkhbayar, Khayankhyarvagijn Terbish), they summarize more than 100 years' study of the Mongolian herpetofauna, from Przewalski, Kozlov, and other famous Russian explorers of Central Asia up to the present time, and can be used as a basis for the future herpetological research of this region.

During the last decade, special attention has been given to long-term research on the herpetofauna of tropical forests of southeast Asia. Darevsky and Orlov personally have led more than 10 expeditions to Vietnam beginning in 1982; as a result of this herpetological study of Vietnam, and also of Laos, Nepal, and Sikkim (India), a large number of species endemic to tropical forests that are difficult to access, in the coastal area and adjacent islands, were collected. A number of new species and subspecies of frogs, lizards, and snakes, and two new genera of scincid lizards, were described. This research is one of the central programs of the Department of Herpetology today and is conducted in concert with herpetologists from the USA (Field Museum of Natural History and Museum of Vertebrate Zoology, University of California at Berkeley) and Canada (Royal Ontario Museum).

The integrative study of biomorphological diversity in squamates is now being researched by Natalia Ananjeva who is examining different trends of adaptation to the arid and mesic, petro-, and psammophilous lizards and snakes. A major area of interest is the study of integument, using light and electron microscopic methods (especially SEM) conducted during the last decade in cooperation with the Department of Zoology, Kazakh State University (Tatyana Duysebayeva). This research includes a comparative study of different types of scalation patterns and evolutionary trends in different branches of squamates, and also the morphology of derivative structures (skin sense organs, callose scalation) that are of special interest for clarifying questions of ecology, behavior, and phylogeny. Other interesting results were obtained during a comparative study of the egg tooth of squamates.

FIG. 3. Part of the lizard collections, including Galapagos iguanas on the lowest shelf, with staff (from left: Svetlana A. Kalyabina, Julia A. Smirnova) (September 1997).

The Department of Herpetology also is active in conservation of herpetofauna. Ananjeva, Darevsky, Borkin, and Orlov participated as authors or editors in several editions of the "Red Books" of the USSR and of Russia and for some popular books and booklets on animal protection. A book about rare and endangered amphibians and reptiles of the world (Darevsky and Orlov 1988) and collected papers (edited by Darevsky and Vladimir Krever, 1987) on amphibians and reptiles of the protected reserves of the USSR has been published. Captive breeding of rare species is conducted in our department's terrarium and in cooperation with the St. Petersburg Zoo and Tula Zooexotarium, with special focus on rare and endangered species and species that are of special scientific and economic value (parthenogenetic rock lizards, boids, viperids, rare and endangered amphibians and reptiles of Vietnam). Captive breeding of rare frogs, lizards, and snakes of Indochinese tropical forests are being actively developed.

The paleontological activities of Lev I. Khosatzky and Lev A. Nessov have been closely connected with our department. Both of them worked as docents in the Department of Vertebrate Zoology of St. Petersburg State University. Khosatzky mainly studied Neogene turtles of the USSR and described some of the most common turtles from the late Cretaceous of Mongolia. Some of his papers and monographs (Khosatzky and Oleg Redkozubov 1989) were devoted to the Neogene herpetofauna of Moldavia. The paleoherpetological collection of our department was founded as a result of his work. He was the graduate supervisor for Ananjeva and Borkin during their study at the University. Khosatzky also trained many paleo- and neoherpetologists, among them Nessov, who made great contributions to the study of Jurassic, Cretaceous, and Paleogene amphibians and reptiles of the USSR. During 25 years of his scientific work, he published 67 papers and one monograph (Nessov 1995) devoted to fossil amphibians and reptiles. A second monograph was published after his death (Nessov 1997). His publications include descriptions of 44 amphibian and 92 reptilian taxa (Averyanov 1996). The most important among them are descriptions of the oldest salamander (the middle Jurassic *Kokartus*), one of the last labyrinthodonts, *Ferganobatrachus* (late Jurassic), rare Cretaceous salamanders and frogs, numerous new taxa of Jurassic, Cretaceous, and Paleogene turtles, rare forms of lizards (among them the oldest amphisbaenians and xenosaurids), sea snakes, crocodiles, dinosaurs, and pterosaurs. Most of the materials studied by Nessov are now deposited in our institute's paleoherpetological collection. Some current studies in paleoherpetology are carried out by Alexander Averyanov and Igor Danilov. The latter is involved now in studying important Mesozoic turtles from Mongolia.

Studies on speciation conducted in our department have had wide international recognition. One mechanism of interest—so called "neorthodoxal speciation"—is associated with clonal reproduction, hybridization, and polyploidy. A long series of publications on the unisexual rock lizards of the Caucasus (Ilya Darevsky, Larissa Kupriyanova) has become a classic study of speciation mechanisms. They use an integrative approach involving morphological, karyological, and cytological methods, skin graft technique, protein electrophoresis, and analysis of repetitive DNA sequences that allow an estimate of the significance of hybridization in the origin of parthenogenetic species, their relationships with bisexual species, and the role of interspecific hybridization (between parthenogenetic females and males of potential parental species) in the origin of triploid males. New data about parthenogenetic agamids and geckos, with descriptions of new species, have been obtained from Vietnam. The analysis of hybridogenous speciation in fish, amphibians, and reptiles led them to new concepts of gradual hybridization of unisexual and bisexual forms that explains the origin of polyploid complexes in vertebrates.

FIG. 4. Present staff of the Department of Herpetology, including students (August 1997). Left to right: Leo J. Borkin, Konstantin D. Milto, Natalia B. Ananjeva, Larissa K. Johanssen, Ilya S. Darevsky, Igor G. Danilov, Larissa A. Kupriyanova, Andrei A. Barabanov (first-year student at Saint Petersburg University), Nikolai L. Orlov.

Important results were obtained from a study of European green frogs of the hybridogenous *Rana esculenta*-complex (Leo Borkin) in the former USSR, Poland, Germany, and Sweden. Using flow DNA-cytometry, evidence of selective elimination of chromosomes of one of the parent's genomes during gametogenesis was obtained in hybrid males. A large variety of mixed population systems has been discovered in the territory of the former USSR (hybrid frogs coexisting only with one of the parental species, or with both parental species; or existing mostly as males or females or living without parental species at all).

Another interesting case of neorthodoxal speciation is the polyploid complex of green toads in Central Asia that also has been studied by cytogenetic methods. An analysis of samples from Kazakhstan, Kirgizia, and other republics permit an understanding of the trends of geographical and altitudinal distribution of diploid and tetraploid species, and zones of sympatry and hybridization (with sterile hybrids) have been discovered. It has been hypothesized that tetraploid toads, which have a vast distribution from the Caspian Sea to Mongolia, originated through autopolyploidy, i.e., without hybridization.

Comparative karyological studies of lizards (Larissa Kupriyanova) have led to important conceps about their chromosome evolution. Ideas about chromosome variation in lacertid lizards and evolution on the karyological level have also been formulated.

Publications, Current Collections, and Other Activities

From 1977 to 1990, eight volumes of collected papers in herpetology were published by the Zoological Institute. A list of the world's herpetofauna (Ananjeva, Borkin, Darevsky, and Orlov) with their common names in four languages (Russian, English, German, and French) was published in 1988. In 1993, these herpetologists, together with Folium Publishing Company, founded a new English-language journal—the *Russian Journal of Herpetology* —that has been published twice a year, beginning in 1994 (web address: http://www.folium.ru/rjh).

A large number of specimens of amphibians and reptiles collected by Russian zoologists and explorers over several generations are stored in the Department of Herpetology; our department houses one of the largest collections of herpetofauna of Russia and adjacent countries, including Central and Southeast Asia. There are now 5444 registration numbers of amphibians and 20568 of reptiles (a registation number represents one sample from one locality). Ours is the largest herpetological collection in Russia, as well as in all of the countries formerly part of the USSR; it contains numerous type specimens. Recently, the collection was moved to a special fire-proof storehouse outside the city, although all accessioning is conducted at the old institute. The tedious job of moving, rearrangement in the new storehouse, and inventorying is possible only due to the hard work and enthusiasm of collection managers Larissa Johanssen, Igor Danilov, and Konstantin Milto. Collections of fossils and skeletons of recent species were organized and increased considerably during recent years due to the efforts of Ananjeva and Danilov.

For a long time, the Department of Herpetology has been the center for herpetology in the USSR. Ilya Darevsky was the head of the Herpetological Committee of the USSR Academy of Sciences, Natalia Ananjeva was a Secretary of this Committee, and staff of our department actively participated in the organization of all the Soviet Herpetological Conferences (in 1964, 1968, 1973, 1977, 1981, 1985, 1989). During this period more than 30 herpetologists from all the parts of the Soviet Union, Mongolia, and Vietnam have received their Candidate and Doctoral Degrees under Darevsky's guidance. In 1989, Darevsky was elected as President of Nikolsky's Herpetological Society, the Russian national herpetological society. Members of our department also have played essential roles in the establishment and running of the World Congress of Herpetology, beginning in 1982.

Our international projects and programs have become of increasing importance during the last decade. One of the most important is our longterm joint program of research in arid territories of the Palaearctic region (with scientists at the Museum of Vertebrate Zoology, University of California at Berkeley [T. J. Papenfuss], Washington University in St. Louis [J. R. Macey], and the Chengdu Institute of Biology, Academia Sinica [Zhao Ermi and his colleagues]).

FIG. 5. Ilya S. Darevsky and Nikolai L. Orlov, during expedition to Vietnam (October 1994).

In 1989, 1990, 1992, and 1995, Ananjeva and Orlov conducted extensive expeditions in Central Asia. Herpetologists from the Royal Ontario Museum, headed by R. W. Murphy, worked on Caucasian rock lizards together with Darevsky and Kupriyanova. The new program of herpetological research in Indochina is conducted together with colleagues from the Royal Ontario Museum, Museum of Vertebrate Zoology, and Field Museum of Natural History. Borkin has done long-term cooperative studies with herpetologists from Canada and Japan on the study of brown frogs of the Palaearctic and in the study of the hybridogenous complex of European green frogs with herpetologists from Germany, Poland, and Sweden. Finally, a joint project on viperid snakes has been done by Orlov and Boris Tuniyev with Göran Nilson and Claes Andrén from Göteborg University, Sweden.

After dissolution of the USSR, cooperative projects with herpetologists from the former member republics (Turkmenistan, Kazakhstan, and Kirgistan) continue to be developed. The Second Asian Herpetological Meeting was organized with the participation of members of our department in Ashgabat, Turkmenistan, in 1995 and the Third Asian Herpetological Meeting will be held 1–5 September 1998 in Almaty, Kazakhstan.

Acknowledgments.—I am very thankful to Kraig Adler who encouraged me to prepare this paper and for correcting my English.

Facultative paedomorphosis is an environmentally-induced polymorphism (polyphenism) of some salamander species in which larvae either transform into terrestrial forms that mature on land to become metamorphic adults, or retain their larval morphology and aquatic existence while becoming sexually mature paedomorphic adults (Semlitsch 1985; Whiteman 1994). Facultative paedomorphosis has been found in a variety of species in the families Ambystomatidae and Salamandridae (e.g., Brandon and Bremer 1966; Collins 1981; Eagleson 1976; Harris 1987; Kalezic and Dzukic 1985; Kalezic et al. 1989; Patterson 1978; Shaffer 1984; Sprules 1974a). This polymorphism is especially well known in the *Ambystoma tigrinum* complex, occurring in several of the currently recognized subspecies (Collins 1981). However, paedomorphosis appears to be rare in the eastern tiger salamander, *A. t. tigrinum*; published accounts are limited to a few specimens from Michigan (Hensley 1966; Jones et al. 1993). Here we document facultative paedomorphosis in an eastern tiger salamander population in Indiana.

We collected tiger salamanders from Sharon Chapel pond, a permanent, 1.2 ha borrow pit pond located 9.6 km west of West Lafayette, Indiana, USA, in the Purdue University Horticultural Farm. We obtained paedomorphic individuals during May 1992 while collecting *Rana catesbeiana* tadpoles with plastic minnow traps baited with liverwurst wrapped in cheesecloth. We also sampled for tiger salamanders using minnow traps in March 1993, and both minnow traps and a 50 m section of drift fence with pitfall traps (for breeding metamorphic adults) during March 1994. Each individual was transported to the laboratory, identified to morph (by presence or absence of larval characters such as gills and tailfin in sexually mature individuals) and sex (by the presence [males] or absence [females] of large darkened papillae posterior to the slit-like [males] or rounded [females] cloaca), and measured for various morphological parameters including snout–vent length (SVL; using a metric ruler) and mass (g; using an Ohaus model GA-110 balance). After taking these measurements, we marked salamanders with individual toe clips and released them back into the pond.

We compared the SVL and mass of metamorphic and paedomorphic adults using a two-tailed t-test. Recaptured individuals were excluded from analyses, and we did not analyze differences between sexes because few females were captured. We also calculated mean growth rates (SVL and mass) for recaptured metamorphic adults.

We captured five paedomorphic adults in 1992 (3M:2F; Fig. 1, 2), eight metamorphic adults in 1993 (all males), and eight metamorphic adults in 1994 (six recaptures, two new females). One of the six recaptures had been captured originally as a paedomorphic male in 1992, and the others were caught as metamorphic adults in 1993. Paedomorphic adults were significantly larger than metamorphic adults in both SVL and mass (Table 1). Mean growth rate (± 1 S.E.) for recaptured metamorphic males was 0.7 (± 1.0) mm SVL and 0.9 (± 2.8) g mass over a single year. The transformed paedomorphic male, in contrast, grew 1.5 mm/yr SVL and lost 22.1 g/yr mass over a two-year period.

Morphologically, paedomorphic salamanders differed from those found in Colorado populations of the Arizona tiger salamander, *Ambystoma tigrinum nebulosum* (Whiteman, pers. observ.). Heads of paedomorphic adults from Sharon Chapel appeared less shovel-shaped and flattened (Fig. 1) and tails wider (apparently laden with fat deposits; Fig. 2) than those of the western subspecies.

The presence of facultatively paedomorphic salamanders has usually been associated with the absence of fish in permanent ponds and lakes (Collins 1981; Sprules 1974a); however, a variety of abiotic and biotic factors influence the production and maintenance of these alternative morphs (e.g., Harris 1987; Jackson and Semlitsch 1993; Licht 1992; Semlitsch 1987a; Sprules 1974b; Whiteman et al. 1996). Sharon Chapel pond is permanent, but contains small predatory fish (bluegill, *Lepomis macrochirus*) and bullfrogs (*Rana catesbeiana*), both of which are known to consume larval amphibians (e.g., Bury and Luckenbach 1976; Moyle 1973; Semlitsch 1987b). However, European millefoil (*Myriophyllum spicatum*) was extremely dense in the pond and may have provided a refuge from these predators. We speculate that individuals became paedomorphic in this population because of favorable aquatic growth conditions (abundant food, low competition, or low predation; Werner 1986; Wilbur and Collins 1973). The large body size of paedomorphic adults (Table 1) provide some support for this hypothesis.

We did not capture any paedomorphic individuals after 1992. Because one paedomorphic salamander was recaptured as a metamorphic adult, some or all of the paedomorphic salamanders in the pond may have transformed.

TABLE 1. Mean (± 1 S.E.) body size measurements for paedomorphic and metamorphic eastern tiger salamanders from Sharon Chapel pond in Tippecanoe County, Indiana.

	Paedomorphic Adults	Metamorphic Adults	t	p
SVL (mm)	131.6 ± 2.4	117.8 ± 2.2	3.83	0.02
Mass (g)	117.1 ± 3.5	44.23 ± 2.1	19.05	<0.0001
N	5	10*		

*N = 9 for mass

The appearance of paedomorphic eastern tiger salamanders in this Indiana locality suggests that other polymorphic populations might also exist throughout the range of this subspecies, and that

FIG. 1. Paedomorphic eastern tiger salamander from Tippecanoe Co., Indiana.

sampling permanent wetlands might reveal such populations. It also suggests that regardless of their current prevalence, paedomorphic adults may have been historically common in eastern tiger salamanders. The large amount of anthropogenic change which has occurred during the last two centuries in the eastern and midwestern United States has had a significant impact on aquatic habitats and the organisms that live in them (Dahl 1991; Lannoo 1998; Russell 1989; Tiner 1984), and might have had similar negative effects on facultatively paedomorphic salamanders. Wetland destruction, fish and bullfrog introductions, and agricultural and industrial effluent have all been suggested as possible factors influencing the rarity of facultative paedomorphosis in the Midwest (Larson 1998; Whiteman and Howard 1998). Such factors could also apply to much of the rest of *A. t. tigrinum*'s range as well.

FIG. 2. Top view of paedomorphic eastern tiger salamander. Note quarter for size comparison. SVL = 139 mm, total length = 255 mm, mass = 124.2 g.

Acknowledgments.—We thank B. Thompson for allowing us use of the pond at the Purdue Horticultural Farm, S. Wissinger for technical information, and B. Shaffer, T. Jones, and N. Buschhaus for comments on the manuscript. This research was supported by an Indiana Academy of Sciences Research Grant, a Purdue Research Foundation Fellowship, and a NSF Dissertation Improvement Grant (DEB-91-22981).

Rediscovery of the Agamid Lizard *Calotes kinabaluensis* de Grijs (Lacertilia: Agamidae) in Borneo, with Notes on its Habitat

ROBERT F. INGER
Department of Zoology, Field Museum of Natural History
Chicago, Illinois 60605, USA
e-mail: inger@fmnh.org

and

MAKLARIN LAKIM
Kinabalu Park, Sabah Parks, P.O. Box 10626
88806 Kota Kinabalu, Sabah, Malaysia

Mount Kinabalu, Sabah (northern Borneo), is one of the better explored areas of Southeast Asia from the herpetological standpoint. Yet much uncertainty still remains. *Calotes kinabaluensis* de Grijs, a relatively large agamid (snout-vent length 133 mm, total length 448 mm), was described 60 years ago on the basis of a unique holotype collected in 1900 at "Mount Kina Balu" (de Grijs 1937). Ota and Hikida (1996) reported the second known individual (snout-vent length 143 mm, total length 474 mm), collected in the late 1970's (date imprecise) from "Kinabalu Park." As Kinabalu Park, which covers most of the forested mass of the mountain, runs from 200 to 4100 m above sea level and covers a variety of forest types, the habitat of *C. kinabaluensis* is uncertain.

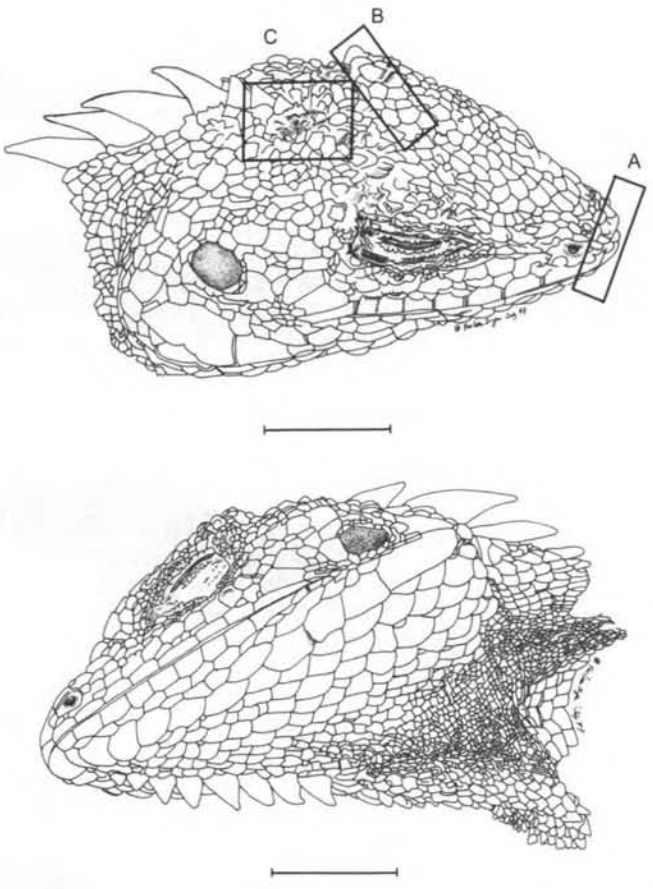

FIG. 1. *Calotes kinabaluensis*. Upper, oblique view of side and top of head. Lower, oblique view of underside of head. Areas marked A, B, C are enlarged in Fig. 2. Scale bars equal 10 mm.

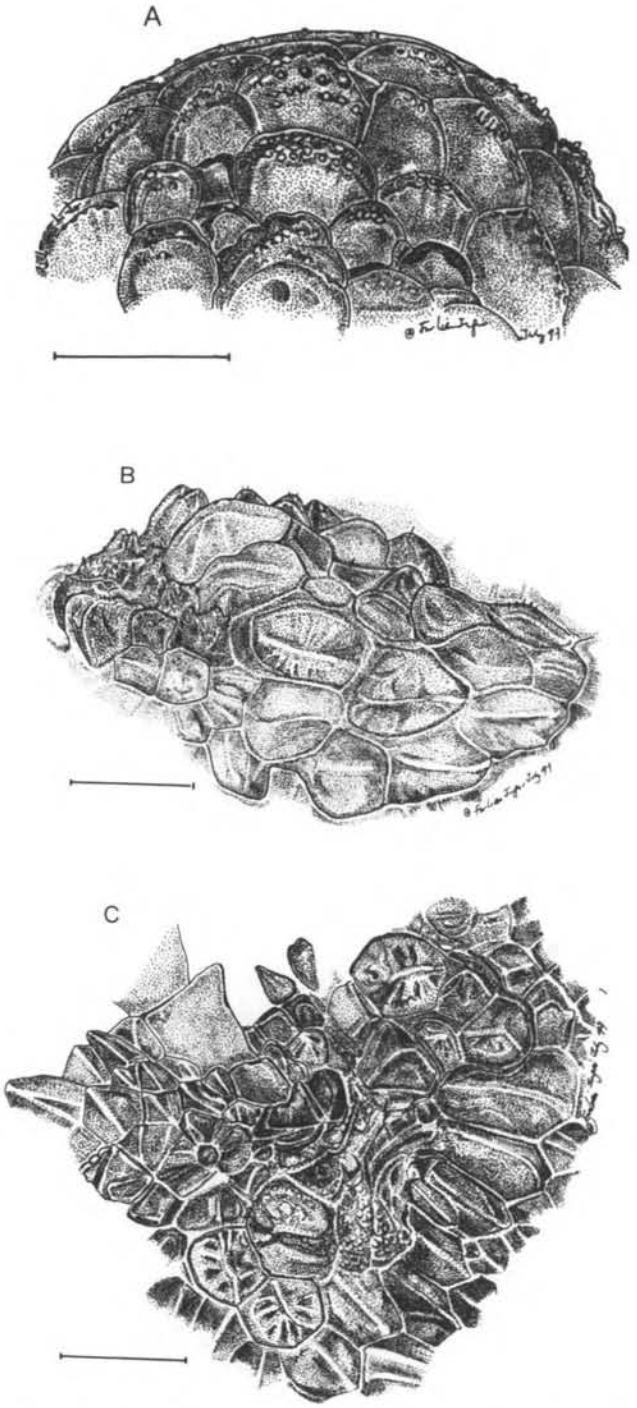

FIG. 2. *Calotes kinabaluensis*, neotype. A. Dorsal view of end of snout. Scale bar equals 2 mm. B. Section across frontal and supraocular region. Scale bar equals 2.5 mm. C. Parietal region and base of nuchal crest. Scale bar equals 2.5 mm.

We report here a third specimen (Sabah Parks 02670) collected in primary lowland rain forest (forest designation after Kitayama, 1992) at 900 m at Sayap, Kinabalu Park, on 23 March 1997. This specimen was collected at night resting on a leaf of a shrub 0.2 m above ground and 1.5 m from a small stream. The long tail and long limbs, as well as the few observations of this species, suggest that its usual stratum is the canopy.

The Sayap specimen has a snout-vent length of 130 mm and a total length of 428 mm. It agrees with the original description (de Grijs 1937) and the expanded description presented by Ota and Hikida (1996). In life the head and body of the Sayap specimen were green. The trunk had chocolate brown and black spots forming bands. Ventrally the body was brown with green spots. The tail was mostly brown with small green areas.

Ananjeva et al. (1991), in a survey of skin sense organs in iguanian lizards, reported that *Calotes mystaceus* had scale organelles on supralabials, nasals, postoculars, postparietals, and mentals. Ota and Hikida (1996) observed "...some marginal scales with short hair-like sense organs associated with pits" on their specimen of *C. kinabaluensis*. In the new specimen of *C. kinabaluensis* scale organelles, most of them knob-like and surmounted by hairs, appear on the scales on top of the snout (Figs. 1 and 2) and on the supralabials, canthals, supraciliaries, supraoculars, and the scales at the rictus behind the labials.

Acknowledgments.—We are grateful to the Director of Sabah Parks, Datuk Lamri Ali, and the Assistant Director, Mr. Francis Liew, for support of the field research. We are also grateful to Messrs. Paul Imbun, Johny Sani, and Rashid Yusof for information on the collections made by them at Sayap. The drawings are the work of Tan Fui Lian Inger.

**Author to whom correspondence should be sent*

Although most species of anurans breed in aquatic environments, breeding usually occurs in shallow water or on land beside water (Jameson 1955, Wells 1977). Underwater breeding behavior is extremely rare, occurring in the Pipidae and some members of Leiopelmatidae and Ranidae. *Bufo torrenticola*, an inhabitant of central Japan, is an unusual toad, for it breeds on the bottom of pools of fast-flowing mountain streams (Maeda and Matsui 1989). This paper provides the first quantitative study of the underwater breeding behavior of *B. torrenticola*.

Study site.—This study was conducted on a branch of the Hirakura River (34°27'N, 136°15'E), in Mie Prefecture, central Japan (see Tsuji and Kawamichi 1996a, for details). Field observations were made at a major breeding pool located mid-stream (elevation 500 m, Tsuji and Kawamichi 1996b), from 6–17 April 1991. This pool was elliptical in shape (16 x 7 m), with a sloping waterfall about 10 m high at the upstream end. The water was 90 cm deep in the center and shallower near the shore. The pool's right bank consisted of a rocky cliff, and the left bank was a wooded slope. The pool's rock bottom was partially covered with loose rocks of various sizes, gravel, and sand. The current was fast along the right shore, but water was relatively still along the left shore. The water temperature ranged from 8.5–13.0°C during the study period.

Methods.—The toad population in the breeding pool was censused 44 times at night, and 18 times during the day, at intervals of 2–8 h, throughout the 12-day breeding period in 1991. Oviposition occurred over six days in the latter part of this period. Most of the toads detected in the pool were captured and individually marked (see Tsuji and Kawamichi 1996a, for marking technique). During each census, the location of lone males, lone gravid females, and amplectant pairs in the pool were noted on maps. We used a clear plastic box for viewing underwater to observe toads in deeper parts of the pool. Despite the use of a 4.5-

TABLE 1. The cumulative number (percentage) of observations of male and female *Bufo torrenticola* in three positions. [a]Excluding attacked paired females. [b]One on the trail near the pool.

	Submerged	At surface	On land	Total
Males	825 (87.7)	66 (7.0)	50 (5.3)	941
Lone	720 (86.1)	66 (7.9)	50 (6.0)	836
Struggling	105 (100)	0	0[b]	105
Females	419 (93.1)	20 (4.4)	11 (2.4)	450
Lone	9 (75.0)	2 (16.7)	1 (8.3)	12
Paired[a]	374 (93.0)	18 (4.5)	10 (2.5)	402
Attacked paired	36 (100)	0	0[b]	36

volt headlamp and a 6-volt flashlight to observe toads at night, the toads did not appear to be disturbed by our presence. After completing field investigations, the maps were divided into 120 quadrats (1 m x 1 m), and the number of toads in each quadrat was determined and used for analyses. Only single males, single gravid females, and pairs that were not ovipositing were included in quadrat counts. The water depth for each quadrat was determined as the deepest point for each quadrat. Toad positions were categorized into three types: 1) submerged; 2) at surface—head or upper part of body above water at shore; and 3) on land—positioned on land around shore.

When toad-balls (male[s] clinging to a pair) were found, their location was noted on maps and the numbers of male(s) clinging to a pair was counted. Males clinging to a pair in a toad-ball were referred to as "struggling males," while the focal pair of the toad-ball was referred to as the "attacked pair." When the number of struggling males in a toad-ball could not be counted exactly, a minimum estimate of toads that could be counted was used.

Results.—A total of about 200 males (including amplectant males) and 100 females was captured and marked in the pool during the breeding period (see Tsuji and Kawamichi 1996a). Combining data among censuses, the cumulative number of observations of male toads in the pool was 941, and 450 observations of females were made (Table 1). These figures include multiple observations of some individuals.

There was a significant difference between males and females in the three positions, submerged, at surface, or on land (χ^2 = 9.97, df = 2, $P < 0.01$). However, the percentage of submerged toads was about 90% for each sex, with relatively low numbers occurring at the surface or on land (Table 1). With the exception of one of each sex, all toads at the surface or on land were found at night.

The cumulative number of toads observed per quadrat over the breeding season ranged from zero to 84 (mean ± SD = 10.1 ± 14.0) for males and from zero to 32 (5.8 ± 6.9) for pairs not ovipositing. Both sexes were more widely distributed in the pool at night than during the day. Males occurred in 81 of 120 study quadrats (67.5%) at night, and in 40 (33.3%) during the day. Pairs that were not depositing eggs occurred in 68 of 120 quadrats (56.7%) at night, and in 43 (35.8%) during the daytime. Submerged males were found in 82 (68.3%) of the 120 quadrats, and pairs were found in 71 (59.2%) quadrats.

Using the data from six censuses conducted between 1500 h on 11 April and 0800 h on 12 April, during which breeding activity was greatest, the mean number of toads observed per census was 29.2 ± 6.4 (range = 22–37) for males and 16.5 ± 3.0 (range = 12–20) for pairs, and they occurred in 21.5 ± 4.8 quadrats (range = 14–27) and 13.5 ± 2.1 (range = 10–15), respectively. The mean number of toads observed per occupied quadrat per census was 1.37 ± 0.14 (range = 1–8) for males and 1.22 ± 0.11 (range = 1–3) for pairs.

Egg-strings were found in 8 of 120 quadrats (6.7%), with over 80% of all egg-strings concentrated in two adjacent quadrats. A huge mass of egg-strings was formed on one of these two quadrats, thus it is referred to as the communal oviposition site.

Lone females were observed only 12 times in just eight quadrats, with most of them in water less than 30 cm deep (Fig.1) and less than 1 m from the right shore of the pool.

The cumulative number of submerged toads observed in each quadrat was positively correlated with water depth (males: r = 0.630, N = 82; pairs: r = 0.566, N = 71; $P < 0.001$ for both; Fig.1). When I removed struggling males or attacked pairs in submerged, the cumulative number of submerged toads observed in each quadrat was still positively correlated with water depth (males: r = 0.609, N = 82; pairs: r = 0.521, N = 71; $P < 0.001$ for both). However, males and pairs differed in their distribution patterns; males were most frequently found in the deepest quadrat (90 cm deep), whereas pairs were mostly at the communal oviposition site which was 40 cm deep (Fig. 1). Most of submerged males actively moved around the pool bottom, possibly searching for females.

A total of 36 toad-balls, all submerged, were found in the pool (Table 1). Toad-balls were found in 17 of 99 occupied quadrats (17.2%), and 15 (41.7%) toad-balls were found in three quadrats in the deeper part (> 80 cm deep) of the pool. Struggling males represented 12.7% of all submerged males, while attacked pairs represented 8.6% of all submerged pairs (Table 1). The cumulative number of both struggling males and attacked pairs was positively correlated with water depth (males: r = 0.569, pairs: r = 0.556; N = 17, $P < 0.02$ for both; Fig. 1). With one exception, no toad-balls were found at the communal oviposition site (Fig. 1).

Discussion.—This study confirms that *B. torrenticola* is unusual in the genus *Bufo*, in that it is an underwater breeder in fast-flowing mountain streams. Underwater activity is a dominant part of the species' typical breeding behavior, because: 1) breeding males and females were submerged on the pool bottom most of time; 2) toad-balls, direct male-male competition for paired females, occurred only underwater; 3) many of the pair formations are considered to have taken place inside the study pool (unpubl. data); and 4) spawning pairs remained underwater and seldom surfaced during the spawning period of 1–2 h (Tsuji and Kawamichi 1998). However, the breeding activity of *B. torrenticola* is not entirely underwater. In the beginning of the

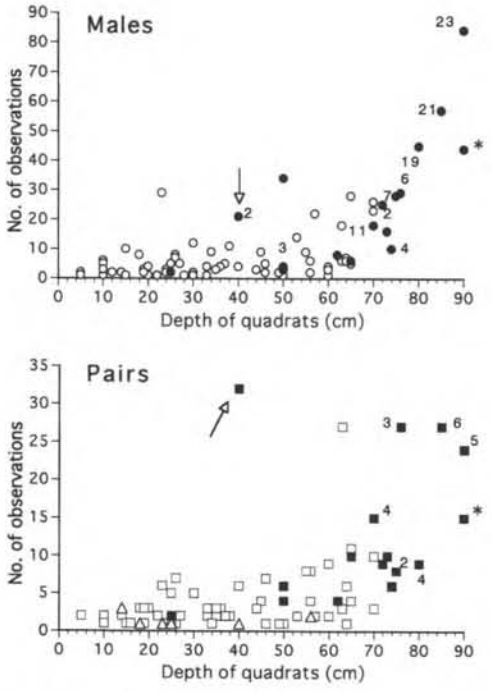

FIG.1. The relationship between the cumulative number of observations of submerged males or pairs, and water depth. Solid symbols: toad-ball observations. Triangles: single gravid females. Figures beside solid circle: number of struggling males (no figure = 1). Figures beside solid squares: number of attacked pairs (no figure = 1). Arrows indicate the quadrat containing most of the communal egg-masses, and asterisks indicate quadrats containing part of the egg-masses. Two quadrats for 4 observations at 50 cm depth.

breeding season, males searched for mates while on migration routes to the stream (Tsuji and Kawamichi 1996a), and they also occasionally waited for females on shore around the pool at night. Such males may be able to intercept newly arriving females to the pool. In general, the males of explosive breeders occur widely around the edges of ponds until spawning commences, whereupon they concentrate around oviposition sites (e.g., *Bufo bufo*, Davies and Halliday 1979; *Rana sylvatica*, Howard 1980). Although this was seen occasionally in *B. torrenticola*, males more often searched and struggled for mates in the deeper parts of the breeding pool. However, lone females commonly were found in shallow water near shore, and paired females were most often found at the communal oviposition site.

Breeding adult *B. torrenticola* showed predominantly nocturnal activity; both sexes were more abundant (Tsuji and Kawamichi 1996a) and more widely distributed in the pool at night than during the day, and almost all toads at the surface or on land were found at night. During the day, however, many toads were found in the relatively deeper parts of the pool. The diurnal breeding activity of *B. torrenticola* may be associated with the early breeding in spring, color dimorphism in visual mate recognition (see discussion in Tsuji and Kawamichi 1996a), and/or underwater breeding.

Besides *B. torrenticola* and members of Pipidae living in the water, underwater breeders are known for the tailed frog, *Ascaphus truei* (Jameson 1955), and the Japanese steam-breeding frog, *Rana sakuraii* (Kusano and Fukuyama 1989), both breeding in fast-flowing streams. Thus, underwater breeding behavior is considered to have evolved independently among anuran groups. The possible benefits of breeding on the bottom of fast-flowing streams include: 1) richly oxygenated waters; 2) low metabolic demands in relatively cold water; 3) relatively stable water temperature; 4) no danger of drying; and 5) predator avoidance (see Olson 1989). On the other hand, possible costs are restricted activity in the water and risk of the eggs being washed away. For two Japanese underwater breeders, *B. torrenticola* and *R. sakuraii*, the most striking adaptation to underwater breeding is enlarged dorsal skin of males (Maeda and Matsui 1989; pers. observ.) that might assist cutaneous respiration in the water and allow them to be vigorously active there.

Acknowledgments.—We thank M. Kishimoto (Miyazaki), T. Mizuta, and T. Teraoka for field assistance; D. H. Olson and two anonymous reviewers for their valuable comments on earlier versions of the manuscript; M. Brazil for assistance with the English manuscript; the staff of Mie University's Misugi Forest for kindly allowing us to study there, and we especially thank the Sakamoto family for their willing help during the time spent living at the study site.

Wildfire and prescribed fire are important influences on pine ecosystems in the southeastern United States (Komarek 1968, 1974; Platt et al. 1988). Although considerable research on the impact of fire on vertebrates due to changes in vegetation structure has been reported, the direct impact of fire on vertebrates is not well known (Means and Campbell 1981). The Louisiana pine snake (*Pituophis melanoleucus ruthveni*) occupies a limited range in eastern Texas and western Louisiana (Conant 1956; Reichling 1995). Within this range it is generally found on sandy soils in longleaf pine (*Pinus palustris*) savannas (Young and Vandeventer 1988). Historically these longleaf pine savannas were maintained by frequent, low intensity ground fires (Komarek 1968; Platt et al. 1988, 1989). In recent decades wildfire frequencies have declined severely due to suppression efforts, and maintenance of these fire climax communities is currently dependent on prescribed fire (Conner and Rudolph 1989; Landers 1987; Platt et al. 1988; Van Lear 1985).

The association of Louisiana pine snakes with longleaf pine savannas and the dependence of these savannas on frequent fire suggests that Louisiana pine snakes have adapted to frequent fire. The influence of wildfires has declined precipitously in recent decades and prescribed fires have only maintained a substantial ecosystem role in limited situations. We have previously hypothesized that these alterations in the fire regime have resulted in apparent declines and local extirpations of Louisiana pine snakes (Rudolph and Burgdorf 1997). The massive increase in woody midstory vegetation and consequent decline of herbaceous vegetation are hypothesized to have had a detrimental impact on pocket gopher populations (*Geomys breviceps*) and ultimately on Louisiana pine snakes.

Since 1993, radio-transmitters (Holohil Systems Ltd., SI-2T transmitters) have been implanted in Louisiana pine snakes at a variety of sites in Texas and Louisiana using the protocol of Weatherhead and Anderka (1984). These transmitters provide a location signal that varies with temperature, providing an estimate of snake body temperature. Preliminary results of ongoing studies demonstrate that Louisiana pine snakes are associated with sandy soils, savanna habitats with abundant herbaceous vegetation, and presence of Baird's pocket gophers (*G. breviceps*). Louisiana pine snakes spend substantial amounts of time underground, primarily in pocket gopher burrow systems, or coiled on the surface adjacent to entrances to pocket gopher burrow systems (Rudolph et al., unpubl.).

Sites where instrumented snakes were located were periodically prescribe-burned by land managers, providing an opportunity to observe snake behavior during exposure to fire. Habitat at all sites consisted of a longleaf pine overstory with a well developed herbaceous understory dominated by bluestem (*Schizachyrium* spp.) and other grasses. Nine snakes were located in burn areas during 1994–97. All nine snakes survived exposure to the prescribed fires with no apparent damage. Six of the snakes were known to be in the burned areas, but were not under observation during the course of the prescribed burns, and it is not known if they were above or below ground at the time of the fires. Three snakes were under observation during the course of the prescribed fires and observations are detailed below.

A prescribed fire on 25 Februrary 1994 burned the area where an adult female Louisiana pine snake was located. At 1155 h the snake was coiled on the surface 1 m downslope from the burrow it used to access a pocket gopher burrow system where it had hibernated. It remained in this position until the approach of the fire at 1438 h. Immediately prior to the passage of the fire the air temperature was 25°C and the transmitter temperature was 27.5°C. The approaching fire was backing downslope at approximately 5 m per min. with flame heights of 0.5–0.8 m. When the fire front was approximately 15 m from the snake, it began moving downslope away from the fire and the burrow entrance. After progressing approximately 2 m the snake reversed direction and moved toward the approaching fire and into the burrow. The fire was 10 m distant as the snake moved underground. The transmitter temperature immediately began to drop from 27.5°C toward the burrow temperature of approximately 11–14°C. Burrow temperatures for this and other observations were estimated from transmitter temperatures of instrumented snakes located in pocket gopher burrows during the general period of the prescribed fire in question.

A prescribed fire on 10 March 1997 burned the area where two Louisiana pine snakes were located. One snake, an adult female, was coiled on the surface at 1145 h. Numerous pocket gopher mounds were evident but, to avoid disturbing the snake, they were not investigated in detail. The snake was in the same position at 1300 h. as the fire approached. Air temperature was 24°C and transmitter temperature was 27.5°C as the backfire with 0.3–0.6 m flame heights moved downslope at approximately 1 m per min. The snake began moving when the fire was 2 m distant and entered a burrow approximately 5 m distant. The burrow presumably allowed access to the pocket gopher burrow system. The fire passed over the snake's burrow entrance at 1352 h. Transmitter temperature at 1400 h was 22°C and dropping toward the burrow temperature of approximately 12–16°C.

The second snake observed on 10 March 1997, an adult male, was located at 1150 h. moving out of a debris pile. It was inadvertently disturbed in the process of being located and rapidly moved approximately 30 m and sought shelter under grass cover. It was still in this location at 1504 h. as the fire approached. The snake was not visible and was not approached closely because of the risk of disturbing it again. As the fire approached the snake, air temperature was 24°C and the transmitter temperature was 23.5°C. The fire was a backfire moving downslope at approximately 2 m per min with 0.4–0.8 m flame heights. The snake maintained its position under grass cover until the flames were within 20 cm at 1516 h. The snake then emerged from beneath the grass cover and moved rapidly across the slope, parallel to and approximately 1.5 m in front of the fire. After moving 15 m the snake reversed direction and moved 95 m in the opposite direction still paralleling the fire front. When relocated at 1524 h. the snake was underground approximately 2 m in front of the advancing fire. The fire passed over the snake's position at 1533 h. The transmitter temperature was unchanged at this time, but began dropping immediately and had reached 18.5°C by 1715 h. After the passage of the fire, no evidence of an entrance to a burrow was located, although numerous pocket gopher mounds were in the immediate vicinity.

These observations suggest that Louisiana pine snakes are not at excessive risk of death or injury because of frequent fire in fire climax pine communities. Snakes located on the surface near known burrow systems simply retreat underground, even if this requires moving toward the advancing fire. Once underground, presumably at the 10–20 cm depth typical of pocket gopher burrows, they are insulated from the effects of the passing fire. Results of our telemetry studies (Rudolph et al., unpubl.) demonstrate that Louisiana pine snakes are underground, or on the surface within a few meters of known burrows, a large majority of the time. Given the large differences at which the snakes apparently detected the advancing fires, it is impossible to reasonably speculate on the possible cues that they might be using to detect fires. It is very possible that different cues are used in different situations.

Snakes on the surface and not near known burrows may be at greater risk. This would occur primarily when snakes were moving substantial distances; ie. between pocket gopher burrow systems, or had sought temporary surface shelter during moves. The third snake discussed above fits this scenario. Even in this situation, behavior of the pine snake served to minimize risk. The snake's immediate behavior was to move a safe distance away from the fire and then initiate what appeared to be rapid searching for a subterranean retreat. This behavior did not cease until the snake gained an underground retreat, even though movement of just a few meters directly away from the advancing fire would have temporarily removed the risk.

The prescribed fires that have largely replaced wildfires in Louisiana pine snake habitat differ substantially from historical fires (Frost 1993; Komarek 1968). Prescribed fires are typically conducted in late winter-early spring whereas wildfires are/were more frequent later in the growing season. In addition, due to a number of concerns, prescribed fires seldom achieve the intensity of many wildfires. These differences presumably influence the interaction of Louisiana pine snakes and fires, however, comparative data are lacking.

The observed behaviors of these Louisiana pine snakes are sufficient to reduce the risk of mortality or injury to a low level from all but the most rapidly advancing fires that occur in the longleaf pine ecosystem. In all of the observed instances the fires were relatively slowly advancing backfires. The potential for mortality or injury to snakes due to rapidly advancing headfires is presumably greater, especially for snakes without immediate access to a

burrow. Wildfires, due to their greater intensity, may pose more of a risk than prescribed fires.

Erwin and Stasiak (1979) and Seigel (1986) reported mortality and injury to several snakes, including *P. melanoleucus*, as a result of prescribed fires conducted in prairie habitats in Nebraska and Missouri. These observations demonstrate that snakes are susceptible to death or injury during fires. The authors of both studies suggested that the timing of fires probably influenced their impact on snakes. Means and Campbell (1981) reported significant mortality of eastern diamondback rattlesnakes (*Crotalus adamanteus*) due to prescribed fires in a longleaf pine ecosystem. All reported instances were of snakes in ecdysis and it was hypothesized that reduced mobility and sensory abilities were associated with the mortality. Similar effects are possible with Louisiana pine snakes, but relevant observations are not available.

Acknowledgments.—We thank J. A. Neal for reviewing earlier drafts of this manuscript. The U. S. Fish and Wildlife Service, Louisiana Department of Game and Fisheries, and Texas Parks and Wildlife Department provided funding for research on *Pituophis* under Section 6 of the U.S. Endangered Species Act. Texas Parks and Wildlife Department issued the necessary scientific collecting permits.

Diel and Monthly Variations in Capture Success of *Phrynosoma cornutum* via Road Cruising in Southern Texas

SCOTT E. HENKE

and

MELISA MONTEMAYOR*
Texas Parks and Wildlife Department
4200 Smith School Road, Austin, Texas 78744, USA

**Present address: Texas Department of Transportation, 1817 Bob Bullock Loop, Laredo, Texas 78043, USA*

Road cruising may be a time-efficient capture method for Texas horned lizards (*Phrynosoma cornutum*) and may yield better capture success per unit effort than systematic searches and funnel and pitfall trapping (Fair and Henke 1997). However, it is unknown if road cruising can be used to assess activity patterns of *P. cornutum*. *Phrynosoma* may show changes in their activity patterns due to season (Fair 1995; Potter and Glass 1931) and ambient temperature (Prieto and Whitford 1971). We hypothesized that *P. cornutum* would be most active and, therefore most vulnerable to collection, during the warmest months, and that *P. cornutum* in southern Texas would exhibit one daily peak in activity during spring and autumn and two daily peaks in activity during summer as suggested by Potter and Glass (1931). We sought to test this hypothesis by collecting information on the success of sighting and capturing *P. cornutum* during road cruising searches throughout a four year period.

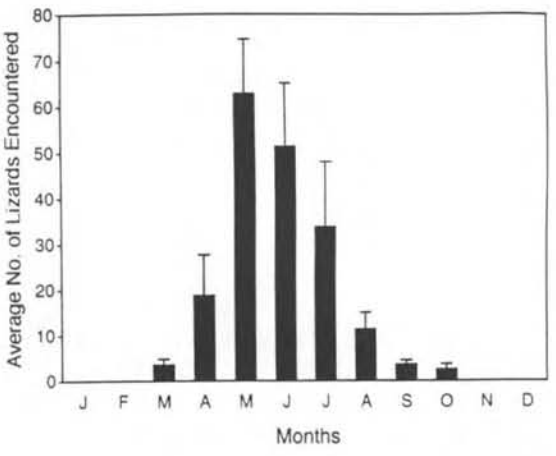

FIG. 1. Average number of *P. cornutum* collected monthly via road cruising during March 1991 to October 1994 in southern Texas. Bars extending above the means are the standard errors of the means. Average number of *P. cornutum* for January, February, November, and December was calculated using three years of data; the average number of *P. cornutum* for the remainder of the months was calculated using four years of data.

TABLE 1. Average number of *Phrynosoma cornutum* collected each month during diurnal hours via road cruising in southern Texas from March 1991 to October 1994.

[3]Means with the same lower case letter are not different ($P > 0.05$) between time periods within the same month.

We marked and released *P. cornutum* on the Chaparral Wildlife Management Area (WMA; 28°20'N, 99°30'W) in southern Texas from March 1991 to October 1994. The Chaparral WMA is a 6154 ha mesquite (*Prosopis glandulosa*) shrubland with sandy loam soils and contains multiple secondary roads. Average monthly temperatures range from 6.1°C in January to 36.1°C in August (Stevens and Arriaga 1985). Mean annual precipitation is 54.6 cm, of which 85% occurs during spring (April and May) and autumn (September and October; Stevens and Arriaga 1985). Lizards were actively sought and captured by road cruising, marked by toe-clipping and the use of passive integrated transponders (Camper and Dixon 1988), and released at site of capture. Because *P. cornutum* are considered diurnal (Stebbins 1954), search efforts were limited to daylight hours. Date and time of day of captures were recorded. Time of day was separated into three time periods: sunrise to 1100 h (morning), 1101 to 1600 h (afternoon), and 1601 h to sunset (evening). Sunrise occurred as late as 0725 h during the winter equinox and sunset as late as 2040 h during the summer solstice. However, an equal sampling effort was maintained throughout the study. Each time period was divided into five 1-h intervals beginning at 0600 h and ending at 2100 h. One randomly selected interval was chosen during each time period and intervals were rotated so that each hour interval within a time period was sampled 73 times per year. A 19.5-km route was searched for *P. cornutum* at a speed of approximately 30 kph during each time period each day.

We used a repeated measures design with months and time of day as main effects and years as replications. The distribution of captures was tested to verify normality with the Shapiro-Wilk test (PROC UNIVARIATE procedure; SAS 1989). A general linear analysis of variance (PROC GLM; SAS 1989) was used to test the main and interactive effects on the number of captures of *P. cornutum*. Multiple comparisons were made using Tukey's studentized range (HSD) test when a significant *F*-test was noted. Statistical significance was inferred at $P < 0.05$. For the purposes of this study, we classified *P. cornutum* as exhibiting one daily peak in activity if lizards were encountered more frequently during the afternoon than at other time periods, and as exhibiting two daily peaks in activity if lizards were encountered with equal frequency during the morning and evening time periods, and less frequently during the afternoon.

A total of 692 *P. cornutum* was collected on 749 occasions during the four year study; 86, 231, 132, and 300 horned lizards were captured in 1991 through 1994, respectively. Forty-three *P. cornutum* (6.2%) were recaptured at least once during the study. Of the recaptures, 35 lizards were recaptured only once, four lizards were recaptured twice, three lizards were recaptured three times, and one *P. cornutum* was recaptured five times.

May yielded the greatest number of captures of *P. cornutum*, followed by June and July (Fig. 1). Cumulatively, these months resulted in nearly 80% of the *P. cornutum* collected. *Phrynosoma cornutum* were not collected nor observed on secondary roads during November through February during any year (Fig. 1). After a seasonal hibernation period, *P. cornutum* in southern Texas generally were first observed crossing roads during the third week of March (i.e., 20, 16, 25, and 26 March during 1991 through 1994, respectively); whereas, they typically were last observed crossing roads prior to hibernation during the second week of October (i.e., 10 October, 15 September, 6 October, and 21 October during 1991 through 1994, respectively).

Number of captures of *P. cornutum* differed by month, time of day, and the interaction of the two main effects ($P < 0.0001$). Due to a significant interaction, separate analyses were conducted on the number of captures of *P. cornutum* per month and by the time of day. During June, *P. cornutum* were encountered most often during the morning (Table 1). However during May, the likelihood of encountering *P. cornutum* on secondary roads was greatest from midday to sunset (Table 1). *Phrynosoma cornutum* exhibited one daily peak in activity only during March, while during the remainder of the year the probability of encountering *P. cornutum* occurred with equal frequency between two or more time periods (Table 1). The earliest and latest time of capture occurred in June and was 0630 and 2046 h, respectively.

Neither of our predictions of *P. cornutum* activity held true. July and August are the warmest months in southern Texas (Stevens and Arriaga 1985); however, *P. cornutum* activity peaked in May and declined with each subsequent month. Perhaps this was a result of *P. cornutum* seeking mates. *Phrynosoma cornutum* breed shortly after spring emergence (Milne and Milne 1950). Also, we predicted *P. cornutum* would exhibit two daily peaks in activity from June through August; however, they were most active during the morning hours of June and July with few occurrences of crossing roads in the evening. *Phrynosoma cornutum* are known to remain near active harvester ant (*Pogonomyrmex* spp.) mounds, their main dietary staple (Whiting et al. 1993), and only leave the area when they cause the ant colony to shutdown

(Munger 1984). Also, lizards retreat to shelter after their body temperature exceeds their comfort zone. The preferred temperature of *P. cornutum* is 38.5°C (Prieto and Whitford 1971). Soil temperatures taken after 1600 h during summer in southern Texas can exceed 50°C (Henke, unpubl. data). Although speculative, perhaps *P. cornutum* in our study spent mornings locating active ant mounds and the remainder of the day engaged in localized feeding and thermoregulation.

Phrynosoma cornutum in our study emerged from hibernation earlier than previously documented (Potter and Glass 1931). Also, daily low temperatures dropped to 11°C during mid-September 1992 (National Oceanic and Atmospheric Administration 1993), which coincided with the lack of *P. cornutum* observed crossing roads after mid-September of that year. Cessation of *Phrynosoma* activity occurs with the onset of cold weather during autumn (Wright 1949).

Researchers in southern Texas can use these data to concentrate their capture efforts during peak activity periods of *P. cornutum*. Also, this information could be used in conservation efforts to educate the public as to the active periods of *P. cornutum* and make the general public aware of *P. cornutum* use of secondary roads. Fair (1995) documented road fatalities of *P. cornutum* as a major mortality source in areas with many secondary roads. To our knowledge, there were no *P. cornutum* fatalities as a result of our surveys.

e-mail: mhasumi@sc.niigata-u.ac.jp

and

FUSAYUKI KANDA
Department of Biology, Hokkaido University of Education at Kushiro
Kushiro 085-8580, Japan

The breeding ecology of the Siberian salamander, *Salamandrella keyserlingii* (Hynobiidae), warrants assessment in Japan. Although this species is widely distributed in Siberia, ranging from the Ural Mountains to Kamchatka, it is restricted to Kushiro Marsh on eastern Hokkaido Island in northern Japan (Mikamo 1955). Kushiro Marsh is a wetland complex in a floodplain along the Kushiro and Akan Rivers, with several small freshwater lakes, extensive reed beds, sedge meadows, and peat bogs (Scott 1991). In 1987, selected areas of this marsh and surrounding hillsides were designated as Kushiro Shitsugen National Park (26,861 ha). The central zone that occupies approximately 25% of this park has special protection by law, and here development is prohibited. In this zone, there is a major breeding population of *S. keyserlingii* (Nakabayashi et al. 1986). However, most other breeding populations of this species are located outside of the National Park and have been adversely affected by development, and consequently have declined within the last decade (Hashimoto 1991; Hasumi and Kanda 1996; Ueda 1988).

Conservation measures have met with limited success due to our lack of knowledge of the breeding habitat requirements of *S. keyserlingii*. Transplantation of individuals of this species from developed areas to within Park boundaries has been attempted. In 1986–1990, a total of 66 adult males, 150 adult gravid females, and 2140 pairs of egg sacs (each breeding female deposits one pair; mean = 197.8 eggs, N = 78, SD = 32.9, range = 111–280, in Otanoshike; Hasumi and Kanda 1996) were transplanted into eight artificial ponds newly made within an area of the Park where this species did not occur (Hashimoto 1991). For these five years, a total of 63 pairs of egg sacs were deposited in this area. Currently, only a relatively small number of egg sacs (at most 41 pairs in 1994; Kushiro-shi, unpubl. data) are deposited annually. For comparison, the past largest breeding population in the present developed area had produced 1036 pairs of egg sacs in 1986 (Hashimoto 1991). There are other studies in which translocations were attempted as conservation measures with success (e.g., Natterjack toads in Britain; Beebee 1996).

Habitat conditions may be suboptimal for breeding at the artificial ponds. It is unlikely that vegetation is unsuitable because the sedges used for oviposition have grown thick in these ponds. However, sedges were not dense at the ponds in 1986 (Hashimoto 1991), and the number of egg sac pairs deposited there in 1986–1990 (0, 4, 27, 16, and 16; respectively by year) indicates a possible delay in the recognition of these artificial ponds as a suitable breeding site. One possible explanation for this low reproductive rate is that these ponds (each measuring approximately 10 x 2.5 m, and about 1 m deep) are too deep for successful breeding. In fact, it is unclear why a water depth of 1 m was chosen for constructing these ponds. The water depth this species requires for breeding habitats is unknown. Other species

have shown associations with oviposition site depth (Crump 1991; Petranka and Petranka 1981; Richter 1997). Thus, our study objective was to examine breeding habitat requirements, focussing on oviposition site depth, for the Siberian salamander in Japan, by determining water depths of natural breeding habitats within a low marsh fen and comparing these depths with water depths of nonbreeding habitats within the same fen.

We conducted this study in a marsh located outside the National Park in Otanoshike, Kushiro-shi, Hokkaido Prefecture, Japan (43°01'02"N, 144°17'38"E; 4 m elevation). This marsh has a triangular area of approximately 20 ha, clipped off with a main road now under construction (Hasumi and Kanda 1996) and two residential sections having lesser roads and abandoned developed areas. The Otanoshike-ogawa River (5–6 m wide) flows slowly through the central region of this marsh from the northwest to the southeast. Along the approximately 30 m distance from the right bank (Fig. 1) of this river, vegetation changes from a composition chiefly of sedges and woody plants (mainly *Spiraea salicifolia*) to a forest that is dominated by an overstory of a single species of the alder *Alnus japonica* and is irregularly interspersed with small open fields. There are many bodies of water on the southeastern edge of this right bank, which collectively form the fen, the breeding habitat of *S. keyserlingii*. This population is located at what corresponds to the southern limit of the distribution for this species.

After sunset, a female deposits a pair of egg sacs side by side in open water near the surface by attaching the adhesive tips of the sacs to dead leaves of sedges. During three consecutive breeding seasons (23 April–7 May 1995, 20 April–12 May 1996, and 11 April–19 May 1997), we marked each oviposition site within the fen every day and recorded maps of oviposition sites after establishing the plots described below. We did not consider the role of plants in accounting for egg sac distribution because sedges were distributed throughout the fen. We carried out afternoon surveys because the water surface on the fen occasionally was iced to the thickness of approximately 1–2 cm in the morning. In addition, the water surface of the river occasionally was iced in the morning. Snow had fallen during the night of 9 May 1996, and approximately 10 cm of snow covered this marsh by the next morning (Hasumi and Kanda 1997). Salamanders in 1996 and 1997 exhibited an indistinct end to the breeding season, and therefore we obtained additional data on 29 May and 30 May, respectively.

Fen water depth was determined by measuring depths across a grid-system placed in the fen. We divided a 50 x 13.5 m fen into 0.5 x 0.5 m plots (N = 2700). Water depths within plots were measured to within 1 cm by averaging five point-measurements. Depths were collected over three days, after breeding activity ceased, 2–4 May 1995. In 1995, as in other years, the bottom of the fen was frozen until mid-May. Because rainfall increased water depths, to estimate depths during spawning at oviposition sites, we adjusted plot measurements by determining a standardized depth for the fen. This was done by measuring daily water depths at 1200 h at a fixed point over the breeding periods, 23 April–7 May 1995, 20 April–12 May 1996, and 11 April–19 May 1997. To standardize plot depth measurements, we adjusted plot-data on the day after eggs were laid. This was done by determining the difference between the single fixed-point depth value on that day and the depth measured after breeding (when plot depths were determined). The difference was added to all plots to determine oviposition site depth.

To map the fen topography, we categorized plot water depths into nine depth classes: ≤0, 1–10, 11–20, 21–30, 31–40, 41–50, 51–60, 61–70, and 71–80 cm. We averaged water depths of a set of nine plots ("plot-cluster," 1.5 x 1.5 m area), consisting of a central plot ("plot-center," 0.5 x 0.5 m area) which was characterized as either "utilized" or "unutilized" for egg sac deposition and eight surrounding plots, in order to characterize breeding habitats of this species. For a plot at the edge of the fen, we averaged water depths of a set of four or six plots. We

TABLE 1. Oviposition sites of *Salamandrella keyserlingii* characterized by water depths within a 50 x 13.5 m fen divided into 2700 plots of 0.5 x 0.5 m in Kushiro Marsh, Japan, during three consecutive breeding seasons. Water depths of a set of nine plots (plot-cluster), consisting of a central plot (plot-center) utilized or unutilized for oviposition and eight surrounding plots, are averaged. Within years, each average depth of plot-cluster is compared with its plot-center depth among those 2700 plots.

			Water depth (cm)				Center vs. cluster

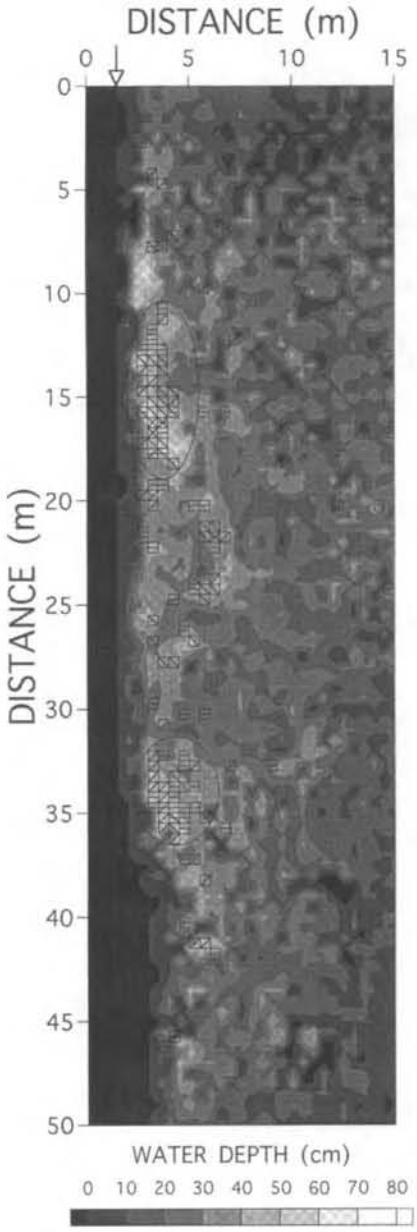

FIG. 1. Topography of a 50 x 13.5 m fen divided into 2700 plots of 0.5 x 0.5 m, showing two dimensional water depths every 10 cm. Left black 50 x 1.5 m area (arrow) corresponds to the right bank. Fen-tussocks are expressed by black (≤0 cm) and many blackish (1–10 cm) areas. Each square area represents a plot utilized for egg sac deposition of *Salamandrella keyserlingii* in 1995 (line from upper left to lower right), 1996 (line from upper right to lower left), and 1997 (horizontal centerline). Ellipses represent "hot spots" (communal breeding locations) in 1995 (upper) and 1996 (lower). Hot spots in 1997 separate into both these ellipses.

compared the average depth of the plot-cluster with the water depth of the plot-center using the Aspin-Welch test when exhibiting unequal variances (Snedecor and Cochran 1980) or Student's t-test ($\alpha = 0.05$).

Breeding activity varied slightly each year, with breeding typically completed in April or May, resulting in the deposition of approximately 60–80 pairs of egg sacs within the fen (Fig. 1; year/date of completion of breeding/number of egg sac pairs, 1995/28 April/78, 1996/10 May/62, 1997/30 May/74). A few egg sacs were deposited in a specific location outside the fen (1996/three pairs, 1997/one pair). All eggs were viable each year.

The fen was relatively shallow throughout and included a great number of tussocks (Fig. 1; black, ≤0 cm, and many blackish, 1–10 cm, areas), each consisting of a mass of sedges assuming a shape like a hummock (Tanaka 1962). Among the 2700 plots, the maximum water depth was 73 cm. In 1995, egg sacs were deposited neither in shallow plots less than 32 cm (2020 plots/74.8%) nor in deep plots more than 66 cm (2 plots/0.074%). Seven and 12 of those 2020 shallow plots were utilized for oviposition in 1996 and 1997, respectively. A total of 130 plots (4.8%) were utilized for oviposition in three years (1995: 78 egg sac pairs, 40 plots; 1996: 62 pairs, 43 plots; 1997: 74 pairs, 60 plots). Among years, 4 of 40 utilized plots in 1995 were utilized again in 1996, and 7 of 40 1995 plots and 4 of 43 1996 plots were reutilized in 1997. Furthermore, only two plots were utilized over three consecutive years.

Plots utilized for oviposition during these three years tended to occur in two places. In 1995, 19 of the 40 plots (47.5%) occurred at one locality; but in 1996, 12 of the 43 plots (27.9%) occurred on another location (Fig. 1). These "hot spots" (communal breeding locations) changed between 1995 and 1996. In 1997, 12 (20.0%) and 15 (25.0%) of the 60 plots with oviposition occurred on those two locations.

Depth of plot-centers did not differ from the average depth of plot-clusters when those centers were utilized for oviposition (Table 1). In contrast, in every comparison, water depths of unutilized plot centers differed from those of clusters. Thus, unused areas appeared to have more variable water depths. Although many plots with apparently suitable depths (i.e., ± 1 SD of the mean) were not utilized, each year the mean depths of these plot-clusters (1995, N = 389, mean = 32.71 cm, SD = 6.48; 1996, N = 841, mean = 29.22 cm, SD = 6.63; 1997, N = 739, mean = 29.81 cm, SD = 6.56; 1995–1997, N = 700, mean = 29.45 cm, SD = 6.38) were significantly lower (each $P < 0.001$) than their plot-centers (1995, mean = 40.7 cm, SD = 4.3; 1996, mean = 35.4 cm, SD = 5.6; 1997, mean = 36.0 cm, SD = 4.8; 1995–1997, mean = 36.0 cm, SD = 4.9).

Female *Salamandrella keyserlingii* oviposited neither in shallow sites nor in deep sites. In addition, they also did not oviposit in sites with moderate depths (i.e., about 40 cm) but small overall areas (0.5 x 0.5 m). These disproportionate depth associations strongly suggest that relatively large areas (1.5 x 1.5 m), having a water depth of around 40 cm, are used as breeding habitats by this species. Our data agree with those of others. For example, in another population, 42 pairs of egg sacs were deposited in a pool (4 x 3 m) having a water depth of 30–40 cm in 1995, but no egg sacs were deposited in an adjacent pool (3 x 1 m) having a water depth of 10 cm (Hasumi and Kanda 1996). Moreover, Nakabayashi et al. (1986) stated for this species that the mean water depth of 13 breeding ponds was 48.2 cm.

Other species have demonstrated associations with breeding site depth. In *Ambystoma opacum*, reduced nest densities occur in the deepest and shallowest sections of a pool (Petranka and Petranka 1981). In *Hyla pseudopuma*, oviposition sites containing deep water receive more eggs than sites with shallow water (Crump 1991). Richter (1997) reviewed water depths used for amphibian oviposition, primarily for North American species, and found that many utilized medium water depths between 10–100 cm. The ponds to which *S. keyserlingii* were transplanted may have been too deep (1 m) to allow successful breeding. The present study suggests that egg laying success could be improved by providing moderate water depths of around 40 cm.

Contrary to our expectations, only two of the 2700 plots were utilized for egg sac deposition of *Salamandrella keyserlingii* over three consecutive breeding seasons. There may be a tendency to use traditional sites at a slightly larger spatial scale, however. For example, there may be a few "hot spot" locations used by the salamanders, and one or more of these locations may be used each year (see Fig. 1). Traditional use of specific breeding areas is common in lentic or lotic breeding habitats (e.g., Tsuji and Kawamichi 1996). This low overlap of "microsites" (plots) used among years presumably reveals the plasticity of breeding habitat use in the Siberian salamander. This notion may contribute to conservation planning of this species.

Acknowledgments.—The senior author thanks all staff members of Onnenai Visitor Center, Kushiro Shitsugen National Park, for their partial support during his stay in Kushiro. We have benefited greatly from the constructive comments of Deanna H. Olson, Klaus O. Richter, and anonymous reviewers. Handling of *S. keyserlingii* is regulated by the Government of Kushiro-shi, and this study was conducted under the permission authorized by this Government. This study was financially supported in part by Grants-in-Aid for Scientific Research from the Japanese Foundation for the Management of Riverine Environments, the Maeda Ippo-en Foundation (Japan), and the Akiyama Memorial Foundation (Japan) for the Promotion of Life Sciences.

The marking of groups or individuals can provide invaluable ecological information. Marked groups can be used to estimate population sizes using standard methods (Krebs 1989). Marks can be used to distinguish among sibships or closely related species in experiments. Individual marks can be used to estimate whether survival and recapture rates depend on phenotypic characters such as morphology, color, or behavior (Lebreton et al. 1992). The power of these methods has made their use widespread for many taxa. Unfortunately, anuran larvae have remained difficult to mark reliably. In setting out to mark tadpoles we found we had two distinct problems: 1) how to anaesthetize tadpoles with minimal, preferably zero, mortality; and 2) how to mark individual tadpoles with unique marks.

Anaesthesia.—We tested three anaesthetics suggested in Fellers et al. (1992): chloretone (chlorbutanol; 1,1,1-trichloro-2methyl-2propanol), benzocaine (ethyl4-aminobenzoate), and tricaine methanesulfonate (TMS; MS-222; ethyl 3-aminobenzoate). We rejected the first two because in preliminary experiments with *Rana temporaria* we found that mortality rates were unacceptably high if anaesthesia occurred within 10 min. At concentrations of 0.01% chloretone, 6 of 48 tadpoles did not recover from anaesthesia and at 0.001% benzocaine, 3 of 48 tadpoles failed to recover. At lower concentrations, anaesthesia took up to 30 min to occur.

At concentrations of 0.02% (1:5000) TMS, 20 of 20 *R. temporaria* tadpoles (mean = 128.8 mg; SD = 24.2 mg) recovered from the anaesthesia. All animals were immobile within 4 min and recovered after about 30 min. Although amphibians vary widely in their ability to tolerate anaesthetics (Fellers et al. 1992), we were later able to mark nearly 1000 tadpoles of *Rana lessonae* and *R. esculenta* that had been anaesthetized this way. The only difficulty occurred when the tadpoles first to recover from anaesthesia began to eat the tailfins of still immobilized animals. This problem was eliminated when tadpoles were placed in separate containers after marking.

Marking.—Donnelly et al. (1992) reviewed methods for marking larval amphibians. We were searching for a method that would not affect the predation risk experienced by tadpoles and therefore rejected fin clips (Turner 1960) and vital stains (Travis 1981) as being unlikely candidates. We were unsuccessful in our attempts to mark tadpoles by injecting organic dyes (Seale and Boraas 1974) and acrylic polymers (Cecil and Just 1976).

Tadpoles were first anaesthetized in a 0.02% solution of TMS and then rinsed in fresh water. We marked the tadpoles with a biologically inert fluorescent polymer (elastomer) from North-

west Marine Technology Inc. The elastomer is available in a variety of colors and when used in combination provides a substantial number of individually recognizable marks.

We injected the tadpoles under the skin, above the musculature of the tail, with a tiny amount (0.2 mm wide; 1 mm long) of fluorescent elastomer using a 1 ml tuberculin syringe and No. 20 needle (19 mm long; 0.4 mm diameter). Injection was done while observing through a stereomicroscope at 6.5X. The procedure can mark animals as small as 8 mm snout–vent length and takes less than 10 s for a single mark. Multiple marks take longer because of the care that must be taken to avoid damaging the tail fin by creating multiple injection wounds. With larger animals it is possible to slide the needle from the tail well up onto the backs of the tadpoles. We found this preferable because it was possible to read the marks more effectively and we had the impression that the marks were less likely to be lost from the back than the tail. Although flexible, the elastomer is not as flexible as a tadpole's tail and can be forced out through the skin. Injections below the tail musculature were not effective.

We have used the material for marking tadpoles in two experiments where we wanted to examine the effect of predators on tadpoles of the closely related *Rana esculenta* and *R. lessonae* which are morphologically indistinguishable and must be identified by electrophoresis. We had hoped to eliminate the cost of electrophoresis for identifying survivors at the end of the experiment.

In the first experiment we marked 280 animals with one of four colors and kept them in four 1000 liter outdoor fiberglass tanks that contained dead *Phragmites* as substrate and actively foraging *Anax imperator* larvae. Out of 160 surviving animals, 136 were still identifiably marked after 8 days. We believe that mark retention would have been higher if we had marked all animals on the back and rejected animals for the experiment that had imperfect marks.

In the second experiment we marked 12 lots of 60 animals with a combination of three marks with the constraint that adjacent marks had to be different colors. With five available colors this gave us 80 unique combinations. The purpose of the marking was to measure survival probabilities of individual genotypes as well as look at the effect of morphology on survival. Although many animals lost marks, the remaining marks and electrophoretic information allowed us to resolve the identity of almost every surviving animal at the end of the experiment. In treatments without predators, survival was up to 100% after five weeks, and some animals had metamorphosed.

Particularly, we were concerned that the marking procedure would change the risk of predation for the tadpoles. We tested these possibilities in two experiments. In the first experiment we used pairs of marked and unmarked *R. temporaria* tadpoles matched for size and exposed them to an *Anax imperator* larva. In four experimental blocks of 12 pairs, marked animals were captured first 22 of 48 times (binomial test; $P = 0.65$). In the second experiment we videotaped the startle response of resting tadpoles and measured the distance travelled in the first 0.2 s (5 frames on PAL). Again, there was no detectable difference in the distance travelled between 20 marked and 20 unmarked tadpoles (t-test; $t = 0.8$; $P = 0.4$)

Conclusions—Tadpoles can be marked with extremely low mortality by anaesthetizing in low concentrations of TMS and injecting fluorescent elastomer subcutaneously. Mark retention is less than 100% but still acceptable for many applications. The marks appear to have little or no effect on tadpole behavior and viability.

Acknowledgments.—Northwest Marine Technology of Olympia, Washington was very helpful in providing test material, and technical advice early in the project. Funding for this research was provided by a grant from the Swiss National Funds to BA. H.-J. Hotz, G. Guex, J. VanBuskirk, A. McCollum, J. Fauth, and R. Altig provided anaesthesia suggestions. C. Rauter and R. Mulheim assisted with the marking. W. Blanckenhorn provided entertainment. The comments of R. Altig and an anonymous reviewer markedly improved the clarity of the manuscript.

Radio-telemetry is an increasingly used procedure to obtain data on the biology of free-living snakes (Reinert 1992, 1994). In Texas and Louisiana we have been using the surgical technique of Weatherhead and Anderka (1984) to implant transmitters in timber rattlesnakes (*Crotalus horridus*) and Louisiana pine snakes (*Pituophis melanoleucus ruthveni*) to obtain information on biology and habitat preferences. In New Jersey transmitters were surgically implanted following the procedure described by Reinert and Cundall (1982), with recent improvements and modifications (Reinert 1992), to investigate the biology and habitat preference of timber rattlesnakes (Reinert and Zappalorti 1988a, 1988b) and northern pine snakes (*P. m. melanoleucus*) (Burger and Zappalorti 1988, 1989, 1991). During the course of this research we have implanted SI-2T transmitters (Holohil Systems Ltd.) in 30 *C. horridus* and 28 *P. m. ruthveni*; and SM-1 transmitters (AVM Instrument Co.) and LF-1 transmitters (L. L. Electronics, Inc.) in 37 *P. m. melanoleucus*, 28 *C. horridus*, and several in other snake species.

Snakes were captured, returned to the laboratory, and surgically implanted with transmitters using the two techniques cited above. In Texas and Louisiana all transmitters were implanted subcutaneously. In New Jersey, all transmitters were implanted in the coelomic cavity (Reinert and Cundall 1982). Snakes were maintained in the laboratory for 2–15 days, with access to a heat source to facilitate healing (Smith et al. 1988), prior to release. Snakes received replacement transmitters at approximately 6–18 month intervals and were entered in the data set repeatedly for each surgery.

In New Jersey, to avoid poor healing or infection during hibernation (Reinert, pers. comm.), snakes rarely were implanted with transmitters after September 1, unless there was a specific need or important reason to do so, e.g., discover an unknown hibernation site, monitor winter body-temperature, or to prevent the loss of a long-term study specimen. In Texas and Louisiana, as research progressed, we suspected that elevated mortality and behavioral anomalies might be occurring in snakes that received implants 1–2 months prior to hibernation in the fall. Observations after release suggested that snakes receiving transmitters in the fall suffered higher mortality during subsequent hibernation than snakes receiving transmitters during spring and summer. In addition, snakes undergoing fall surgeries appeared to exhibit a greater tendency to be present on the surface during the subsequent winter than snakes operated on in the preceeding spring and summer.

We tested these hypotheses using Texas data accumulated over a four-year period between 1993 and 1997. A total of 39 rattlesnake surgeries were performed. Three snakes were deleted from the data set because of causes of death unrelated to surgery (two killed on roads and one died of a pre-existing fungal disease). Five individuals were lost after 1–6 months because of unknown causes and also were deleted. Of the remaining 31 surgeries, 21 were performed between 1 February and 31 August (early surgeries) and 10 were performed between 1 September and 31 October (late surgeries). Six snakes died following surgery and release, 2 of 21 following early surgeries, and 4 of 10 following late surgeries. This difference is significant ($\chi^2 = 4.03$, $P = 0.045$).

Also, we examined the influence of surgery date on timber rattlesnake behavior between a sample of snakes subjected to early surgery, and those subjected to late surgery, specifically the occurrence of the snakes above or below ground during the primary hibernation period (Dec.–Feb.). For this three-month period, snakes subjected to early surgery (N = 19) were on the surface near their hibernacula during only 8 of 74 relocations (10.8%). Of the six snakes subjected to late surgery, 10 of 24 relocations (41.7%), including observations of all six individuals, were of snakes on the surface. This difference is highly significant ($\chi^2 = 11.51$, $P = 0.001$). Of the four snakes that ultimately died during the hibernation period following late surgery, an even higher percentage of relocations were of snakes on the surface (71.4%).

Similar results were obtained for Louisiana pine snakes. A total of 37 surgeries were performed. Eight were deleted from the data set for reasons similar to those for rattlesnakes (three killed on roads, five lost). Of the remaining 29, 25 were early surgeries and 4 were late surgeries. A total of 8 snakes died following surgery and release, 4 of 25 after early surgeries and 4 of 4 after late surgeries. This difference is highly significant ($\chi^2 = 12.18$, $P = 0.001$).

Limited data for pine snakes also are available in relation to surface activity during Dec.–Feb. For the three-month period, snakes subjected to early surgeries were on the surface near their hibernacula during 2 of 37 relocations (5.4%). Snakes subjected to late surgeries were on the surface during 4 of 5 relocations (80%) prior to their deaths. This difference is highly significant ($\chi^2 = 20.02$, $P = 0.001$).

Although the sample sizes are small due to our discontinuation of late surgeries, the differences are unequivocal. Snakes receiving surgically implanted transmitters in the fall experience a significantly higher mortality rate than snakes implanted earlier in the season. They also spend significantly more time on the surface during the subsequent winter. We suggest that individuals subjected to late surgeries that spend more time on the surface during the subsequent winter may be attempting to thermoregulate in a effort to hasten healing of their surgical wounds. Individuals operated on earlier in the season have had more time to heal prior to hibernation and do not exhibit thermoregulatory behavior to the same extent.

How the above scenario translates to higher mortality rates is open to speculation. Several additional observations are perhaps relevant. Of the eight snakes of both species that died following late surgeries, all died within 1–4 months after surgery, in all cases prior to the end of the winter hibernation period for these populations. Of the eight snakes in question, five were observed 7–16 days prior to being found dead. All five were in apparent good health and showed no obvious signs of infection. When verified as dead, two were isolated transmitters, four were skeletal remains and transmitters, one a badly decayed carcass, and one an extremely fresh carcass with no indication of cause of death on necropsy. This last individual was found mid-morning following a night of sub-freezing temperatures. All eight transmitters or remains were on the surface within 5 m of the snake's hibernaculum. We suspect that all eight snakes died on the surface. The

limited information available suggests that predation, and perhaps hypothermia, contributed to cause of death.

If the snakes were more vulnerable to predation while on the surface at low temperature, and this was a factor in the above results, the differences between species may be relevant. Following late surgeries, rattlesnakes survived at a higher rate (6 of 10) than pine snakes (0 of 4). It is possible that even when exposed at low temperatures, the larger and venomous rattlesnakes are better able to deter avian and mammalian predators.

Similar results were observed in New Jersey. A total of 75 early surgeries (April–August) and 9 late surgeries (September–October) were performed on six species of snakes, primarily timber rattlesnakes and northern pine snakes. A total of eight snakes died, four following early surgery (5%) and four following late surgery (44%). This difference is highly significant, $\chi^2 = 14.26$, $P < 0.001$). As observed in Texas, snakes that received late implants (September–October) spent more time basking and remained on the surface longer than those that did not (Zappalorti et al. 1983; Zappalorti and Burger 1985). Additionally, in New Jersey late implant timber rattlesnakes (N = 3) and northern pine snakes (N = 3) emerged sooner in the spring and spent more time basking than snakes receiving early implants.

These results strongly suggest that researchers should refrain from surgical procedures and release of snakes immediately prior to hibernation if possible. These data also suggest that effects of surgical procedures can alter snake behavior, apparently for several months in some situations, following relatively minor surgery. The implications for conclusions based on resulting data are obvious.

Acknowledgments.—We thank Robert Fleet, Fred Anderka, Jim Neal, and Bernie Parresol for helpful comments on earlier drafts of this manuscript. Jim Bockowski, Joanna Burger, Bill Callaghan, Peter Danch, John Erickson, Ray Farrell, Robert Fengya, Ron Ford, Zig Leszczynski, Edward Johnson, Peter Mooney, Howard Reinert, Gianluca Rocco, Mike Torocco, Peggy Zappalorti, Dan Saenz, Chris Collins, John Himes, Mike Duran, and Ray Brown provided technical advice and field assistance. Partial funding was provided by the Endangered and Nongame Species Program, Division of Fish, Game and Wildlife (NJDEP); the New Jersey Chapter of The Nature Conservancy, U.S. Fish and Wildlife Service, Texas Parks and Wildlife Department, and the Louisiana Department of Game and Fisheries. Texas Parks and Wildlife Department issued the necessary scientific collecting permits. The mention of trade names in this publication is for reader information. A Simple Stomach Flushing Method for Small Frogs

CLAUDIO E. G. PATTO

Graduate Program in Ecology, Universidade Estadual de Campinas, C.P. 6109 CEP 13083-970 Campinas, São Paulo, Brazil

e-mail: patto@obelix.unicamp.br

Amphibian dietary studies conventionally employ dissection of fixed animals. This kind of study requires large samples, sometimes difficult to justify in light of amphibian population declines (Wake 1991). Another drawback is the destruction of specimens that could otherwise be useful for other purposes. Moreover, destructive sampling may interfere with population studies by affecting density-dependent processes.

Non-destructive techniques have been used in a variety of dietary studies on large anurans including direct observation (Murphy 1976), stomach eversion, and stomach flushing (Gittins 1987; Legler and Sullivan 1979; McAlpine and Dilworth 1989). These methods, when carried out properly, cause low or no mortality, do not disrupt population processes, and allow individuals to be sampled repeatedly over time. However, dietary studies of small frogs still rely on the collection and dissection of animals (Lima and Moreira 1993; Vitt and Caldwell 1994).

In this report I describe an adaptation of the stomach flushing method for use in small frogs. The method was used to study the diet of the small leptodactylid frog *Hylodes asper* (Müller), an endemic species of the Atlantic forest of southeast Brazil. The range of snout-urostyle length (SUL) of postmetamorphic individuals of this species varies from 20 to 47 mm.

After capture, frogs that were too strong to immobilize with one hand (usually animals >35 mm SUL), were anesthetized for a few seconds in a plastic bag containing cotton soaked with chloroform. In preliminary tests of the procedure, three frogs died after being exposed to chloroform for more than 20 seconds; 10 seconds of exposure seems to be a safe limit. Small individuals were not anesthetized to avoid unnecessary trauma. I used chloroform instead of liquid (Leclerc and Courtois 1993) or injected anesthetic (Letcher 1992) due to the faster recovery rate and because no anesthetic remains on the frog's body.

Anesthetization prevented frogs from using their hands to remove the flushing tubes from their mouths. After anesthetization I introduced a thin flexible silicone tube (Sigma Equipment: 1

mm OD and 0.5 mm ID, 5 cm long) through the mouth into the stomach. When the tube reached the pylorus (the tube could be felt through the wall of the abdomen and the pylorus resisted further introduction), it was retracted approximately 1 mm. I then positioned the animal head down with its mouth pointing into a 100 ml collecting bottle and pumped water through the tube using a 20 ml syringe to wash out the stomach contents. While pumping water, I firmly pressed the lower portion of the abdomen to prevent water from opening the pylorus and allowing the passage of food to the intestine. If I felt additional food through abdominal palpation, I repeated the procedure until all contents had been removed. When the procedure produced no further stomach contents, I repeated it once more to ensure that no food remained.

I toe-clipped study specimens for individual identification. Anesthetized animals were allowed to rest before they were released at the place of capture. In most cases, the frog fled within a few seconds by jumping. After release I preserved the stomach content samples by adding ethanol to the collecting bottle.

During 18 days in the field, I obtained 121 stomach contents from 97 animals. Twenty animals were recaptured, of which 13 were recaptured once and 7 twice. Food was found in the stomachs of 88% of the recaptures (only 3 of the recaptures lacked food). This suggests that the animals were not injured by the procedure and resumed normal feeding activities.

To check if food remained in the frogs' stomachs after flushing, I dissected six animals, three that had been killed in a preliminary collection and three that died during anesthetization trials. None contained food remains in the stomach. I performed the same test on an abundant invader species, *Leptodactylus fuscus* (Schneider). Twenty animals with SUL ranging from 35 to 45 mm were flushed. Food was found in 60% of the animals and no food remains were subsequently found by dissection.

The stomach flushing method can be used on small anurans species as well as larger anurans. Most animals seem to recover after release.The method may be especially useful for dietary analyses of rare, endemic, or protected species, and in studies of population processes or of long term population trends. Furthermore, the whole procedure takes approximately 10 minutes from capture to release, somewhat less than that needed to sample the contents of a fixed animal, and can be performed by one person. The method uses little equipment, but must be performed immediately on freshly captured animals to diminish digestive loss and facilitate prey identification.

Acknowledgments.—I am grateful to Gabriela W. Chaves who gave fundamental logistic support to the field work, and to W. W. Benson, M. A. Schlaepfer, C. Dall'Aglio-Holvorcem, P. R. Holvorcem, M. R. Pie, and M. Orr who patiently contributed with helpful comments on the manuscript. I am also grateful to A. A. Giaretta for informing me of the use of the stomach eversion method. This work has been supported by a graduate fellowship from Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq).

Using Decoys to Capture Spotted Turtles (*Clemmys guttata*) in Water Funnel Traps

PATRICIA MANSFIELD

The hoop trap described by Legler (1960), as well as the D-shaped funnel trap described by Graham (1995), have been used to capture spotted turtles, *Clemmys guttata*. These traps are set partially submerged in water, allowing enough air space for captured turtles to breathe. Funnel traps like these are commonly used to capture aquatic turtles and typically require bait placed inside of them, in order to attract turtles (Graham 1995; Legler 1960; Plummer 1977; Ream and Ream 1966). Although the baited funnel trap has demonstrated its ability to capture spotted turtles in aquatic environments (Dunson 1986; Graham 1995; Klemens 1993; pers. obs.), we have found bait to be an ineffective attractor in the early spring, when turtles emerge from brumation, and water temperatures are below optimum feeding temperatures. In this paper we report on a new technique to attract spotted turtles into water funnel traps in the early spring, using man-made spotted turtle decoys in lieu of bait.

We used a variety of trap capture techniques at our study site in Bridgewater, Massachusetts, including: D-shaped and hoop funnel traps baited with canned sardines in oil; D-shaped and hoop funnel traps set with decoys; and empty control D-shaped and hoop funnel traps. The trapping period was from 6 April to 20 June 1997. All trapping combinations were deployed simultaneously in temporary bodies of water, known as vernal pools. Spotted turtles were also searched for and captured by hand during this same time period.

Decoys were made out of aluminum foil shaped and wrapped with plaster of Paris gauze strips. These decoys lasted for most of the study period but eventually deteriorated. Subsequent decoys have been made out of cement poured in plaster of Paris casts. Each decoy was hand painted with acrylic paints to closely resemble *C. guttata* markings and color. Once the paint dried, decoys were sealed with clear polyurethane. Decoys (one per trap) were then suspended with fishing line, fully submerged in a trap to look as if they were swimming, or mounted to look as if they were standing on the floor of the bottom of a trap.

Traps with *C. guttata* decoys repeatedly and successfully captured both male and female *C. guttata* (5 adult captures: 3 male and 2 female, in 508 trap days). Baited traps yielded only one capture (1 adult female, in 492 trap days). Empty traps (76 trap days), deployed as controls, yielded no captures. Hand captures yielded nine *C. guttata* (5 adult females, 1 adult male, 1 juvenile female, and 2 hatchlings, in 64 search days [a search day is the equivalent of a three and a half hour daytime period of active searching for *C. guttata* on the study site]).

An unexpected result was 3 *Chrysemys picta* captures in decoy traps (1 adult female, and 1 juvenile which was captured twice). In comparison, no *C. picta* were captured in either baited or unbaited traps during our study period.

Our first attempt at using decoys to capture *C. guttata* was in the spring of 1990 at a site where a year earlier we were involved in an extensive spotted turtle population study (Graham 1995). Baited traps from a portion of this site, identified as Vernal Pool 1 and Vernal Pool 2, yielded 13 *C. guttata* captures (5 adult females and 8 adult males) in 584 trap days from 10 May to 16 July 1989. The following year, one decoy trap was set in Vernal Pool 1 and a second decoy trap was set in Vernal Pool 2 from 29 April to 15 May 1990, for a total of 32 trap days. These decoy traps yielded a total of 6 *C. guttata* (3 adult females, 3 adult males).

Although water temperatures below 14°C inhibit *C. guttata* feeding activity (Ernst 1982), these temperatures are not too low for mating activity. Spotted turtles have been observed mating in water temperatures as low as 8.5°C (Ernst 1967).

Because our trapping was conducted in the spring, we believe that our capture success the result of *C. guttata* mating activity. Decoys are routinely used by hunters and biologists to attract waterfowl and deer. Some references comment on commercial turtlers' use of floating decoys to attract sea turtles during mating season (Caillouet 1995; Carr 1952; Rebel 1974). Although scientific literature on using decoys to attract *C. guttata* is scarce, we have found one study that used live adult female *C. picta* along with bait to attract other turtles (Frazer et al. 1990).

Frazer et al. (1990) placed live adult female painted turtles, *Chrisemys picta*, in hoop net traps along with bait, and had significantly higher capture rates in these traps than in traps set only with bait. Unlike our findings, however, these researchers note that the reason for conspecific attraction in their study could not be attributed to an "apparent attraction to sexual activity" because the study was carried out in August, not during spring or fall mating seasons (Frazer et al. 1990). The potential for trapped turtles to attract other turtles into a trap has been noted by others (Cagle and Chaney 1950; Dunham et al. 1988; Plummer 1979). Cagle and Chaney (1950), have suggested that the first turtle in a trap may influence the outcome of the entire catch.

Although we believe that the attraction of *C. guttata* to water funnel traps baited with decoys in the early spring is primarily related to mating behavior, a number of questions regarding the apparent tendency for turtles to be attracted to one another or to turtle decoys remain. For example, does the localized activity (or presence) of decoy turtles (live or artificial) signal to other turtles that there may be a particular resource to exploit (e.g., food, mates, heat, or even basking sites)? Our decoy traps also attracted two *Chrysemys picta*. These results, as well as the findings of Cagle and Chaney (1950) and Frazer et al. (1990), imply that in addition to mating activity, there are likely to be other instances when one turtle may benefit by pursuing another turtle. The use of decoys to attract turtles may help researchers investigate those factors that play a role in a turtle's attraction to other turtles.

Acknowledgments.—Funding for the Bridgewater study was provided by Massachusetts Redevelopment Authority. Stan and Linda Kravitz kindly permitted us to trap on their property. We thank Greg Auger, Rick and Lois McClean, and Jacob Schwam for assistance with this project.

Financial support for the Westborough study was provided by Consolidated Rail Corporation. Terry Graham, along with the field assistance of Andy Graham and Judy Forsberg Santella, shared trapping techniques and collaborated on the May–July 1989 trapping program on the site. Bob Coggins was extremely helpful in obtaining permission for us to return to the Conrail property in the spring of 1990, making it possible for us to set decoy traps.

We thank Jose Rosado for providing access to the Harvard MCZ library and herpetological collections. We also thank Jeff Lovich, Tom French, Joan Milam, and Whit Gibbons for help regarding literature and relevant information on this topic. Preparation for this note was supported by E. C. P., Inc. Finally, we are grateful to James Lazell and Jeff Lovich for their suggestions which helped to improve this manuscript.

A New Capture Technique for Arboreal Lizards

ANN PATERSON
Department of Biology, University of Miami
P.O. Box 249118, Coral Gables, Florida 33124, USA
e-mail: apaterso@fig.cox.miami.edu

Lizards of many species are commonly used in research on behavior, ecology, and population biology. Many types of studies require individuals to be captured and then re-released. Lizards may be captured using a variety of techniques, including pitfall and wire mesh traps (Doan 1997; Simmons 1987), mouse glue traps (Bauer and Sadlier 1992), and baited traps (Zani and Vitt 1995). However, it is often useful to be able to quickly capture specific individuals, which is not always possible when using traps. Commonly used techniques include hand-capture, using a noose attached to the end of a pole (e.g., Medica et al. 1971, cited in Simmons 1987; Tokarz et al., in press), using rubber bands to knock lizards from their perches (Simmons 1987), using baited nooses (Strong et al. 1993), and using scooping devices on the ground (Brattstrom 1996). Several specialized techniques for capturing arboreal lizards have been developed, including the use of sticky poles (Durtsche 1996) and mechanical grabbers (Witz 1996). These techniques can be used with success on a variety of species, notably many anoline lizards.

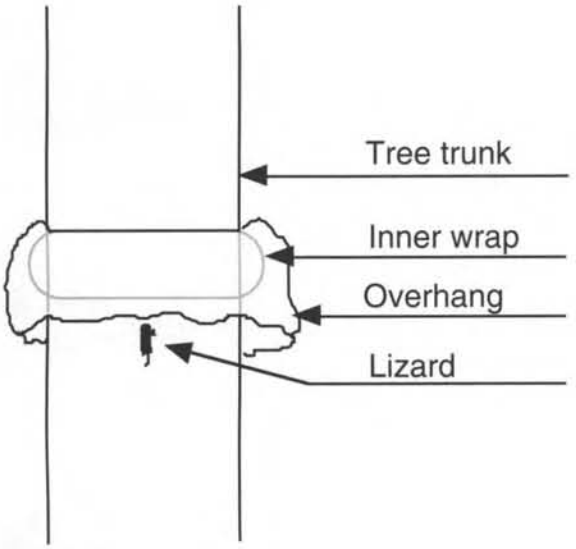

FIG. 1. An overhang is created by first tightly winding bridal veil around the tree (the inner wrap) and then loosely tucking the last wrap of fabric into the top of the inner wrap. When the lizard moves up the tree, it will be trapped between the overhang and the trunk.

However, it can be extremely difficult to capture some arboreal species, particularly those that are small, wary, and/or fast-moving, using the above techniques. Hand capture may be difficult or impossible. Even if these species will allow themselves to be noosed, the thread used for the noose must often be very fine and is difficult to manipulate or see. Although using rubber bands can be effective (Simmons 1987), this technique is often undesirable as it is more likely than others to result in injury to the lizard (Conant and Collins 1991; Witz 1996). Using mechanical devices may be difficult when lizards are easily disturbed, fast-moving, and able to escape to inaccessible refuges. To reliably capture the bark anole, *Anolis distichus*, I developed and used a new, simple technique which may also be applicable to other trunk-dwelling species.

Individual *A. distichus* usually are found on the trunks of trees and generally avoid the ground except when capturing prey. This species is sufficiently wary and agile to make noosing and hand capture almost impossible. Most individuals respond to capture attempts by running up tree trunks beyond reach.

I was able to capture *A. distichus* from the trunks of trees using a mesh barrier to facilitate hand capture. After locating individuals, I approached their trees from the side opposite the lizard and tightly wrapped a mesh barrier (bridal veil fabric, available in many sewing and craft stores) several times around the tree above the lizard (approximately 2 meters above the ground). I tucked the final wrap loosely under the top of the previous layers so that it provided an overhang (Fig. 1). The lizards were reluctant to pass the mesh barrier or to venture onto the ground, so it was possible to capture them by hand in a confined area. If they attempted to pass the barrier they often became caught between the tightly wrapped layer and the overhang long enough to allow capture. They could be easily removed from the mesh without injury.

This method of capture for *A. distichus* is easily used and inexpensive. Other types of similar fabric should work equally well (e.g., mosquito netting). Although not appropriate for some species that will readily escape across the ground, it may be useful for many other trunk-dwelling species.

Acknowledgments.—I thank Stephen McMann, Marion Preest, and Kirsten Nicholson for their many helpful comments. In addition, I thank Sandra Perez for familiarizing me with the use of bridal veil fabric as a tool for capturing and holding bees.

HERPETOLOGICAL HUSBANDRY

Notes on the Captive Maintenance and Reproduction of Oates' Twig Snake (*Thelotornis capensis oatesii*)

SEAN C. FOLEY
Department of Herpetology, Riverbanks Zoo and Botanical Garden
Columbia, South Carolina 29202, USA
e-mail: spfaff@scsn.net

The twig snakes of the genus *Thelotornis* are arboreal, rear-fanged colubrids native to savannahs and coastal forests of eastern and southern Africa and the rainforests of central and western Africa (Branch 1988). Two species are recognized: *Thelotornis capensis* and *T. kirtlandii*. In addition, three races of *T. capensis* have been described: *T. c. capensis, T. c. mossambicanus*, and *T. c. oatesii* (Branch 1988). Information on captive reproduction and husbandry of *Thelotornis* is sparse and few institutions house them. Slavens and Slavens (1996) list two institutions as holding *Thelotornis,* while the ISIS Reptile Abstract (1997) current as of 30 June 1997 lists four institutions as maintaining *Thelotornis* with reproduction occurring only at the Riverbanks Zoo. Recently, the St. Louis Zoo reproduced *T. c. oatesii* using captive born animals acquired from the Riverbanks Zoo (Ettling, pers. comm.). This paper summarizes husbandry, reproductive events, and neonate care of *T. c. oatesii* at the Riverbanks Zoo.

A single, wild-caught adult male was acquired in December 1993 followed by two additional males and a single female (all wild-caught adults) in September 1994. According to Shine et al. (1996), *Thelotornis* are sexually dimorphic in that males have longer tails, smaller heads and thinner bodies. Here, it was possible to accurately sex the adult snakes using these characteristics; however, sexing was confirmed by hemipenial probing (> than 10 subcaudals for males, 1–2 subcaudals for the female). Upon arrival, the snakes were moved into quarantine facilities for 90 days and individually housed in aquaria measuring 61.0 x 40.6 x 30.5 cm. Cage furniture consisted of a potted plant (*Pothos*), several branches, and a water bowl. Heat and light were provided by an incandescent 60 W light bulb placed on one end of the cage. Paper towels and newspaper were used as substrates.

All snakes were offered live or prekilled young mice (6–18 g). One male accepted live mice, while the other three snakes refused. Their natural diet is composed mainly of lizards, frogs, snakes, and rarely, birds (Shine et al. 1996) and in captivity, they readily accepted live *Anolis carolinensis*. Because of the difficulty in obtaining large numbers of *Anolis* and the possibility of introducing parasites to the snakes, it was deemed necessary to wean the snakes off of the lizards and on to mice. First, a small mouse liberally scented with *Anolis* "soup" (minced *Anolis* mixed with water) was offered. If this failed, a live *Anolis* was used as bait. The lizard was either placed in a clear jar within the snake's sight or directly in the snake's enclosure. This elicited an immediate hunting response. A scented mouse was then placed between the snake and the lizard. After the snakes regularly accepted scented mice, the amount of *Anolis* soup was reduced every few feedings until they took unscented prekilled small mice (process took between 1–8 mo.).

TABLE 1. Comparison of egg and hatchling data of six clutches of *Thelotornis capensis oatesii* at the Riverbanks Zoo (R) and St. Louis Zoo (S), and one clutch of *T. c. capensis* by Haagner (H). Egg data: clutch weight, mean egg weight, incubation temperature, and incubation period with N as the number of eggs per clutch. Hatchling data: weight, snout-vent length (SVL), and total length (TL). Means are provided followed by ranges in parentheses and N as the number of hatchlings measured.

	Riverbanks				St. Louis		Haagner
EGG DATA							
Clutch #	R1	R2	R3	R4	S1	S2	H1
Weight (g)	70.5	23.3	82.4	70.0	39.5	31.6	60.6
Mean	6.4	7.8	9.15	6.36	5.64	6.32	6.06
N	11	3	9	11	7	5	10
Incubation temperature (°C)	26.7	28.9	26.7	—	27.8	—	28.0
Incubation period (days)	73–76	59–61	72–76	—	62–63	—	56–57
HATCHLING DATA							
Weight (g)	4.0 (2.0–5.0) N = 10	5.0 (4.8–5.2) N = 3	6.5 (5.0–7.2) N = 7	—	3.7 (3.3–4.2) N = 3	—	3.5 (3.0–3.9) N = 10
SVL (mm)	185 (165–220) N = 6	195 (185–205) N = 3	226.7 (215–233) N = 7	—	175 (146–195) N = 3	—	—
TL (mm)	285.5 (245–320) N = 10	283.3 (275–290) N = 3	354 (340–370) N = 7	—	252.3 (225–304) N = 3	—	310.2 (292–331) N = 10

As soon as the snakes began feeding, they were treated prophylactically with anthelmenthics. A one time dose of praziquantel (Droncit, Miles Inc., Shawnee Mission, Kansas 66201, USA) was administered IM at 7.0 mg/kg. In addition, two doses of fenbendazole (Panacur, Hoechst-roussel Pharmaceuticals, Sommerville, New Jersey 08876, USA) at 1.0 ml/kg and two doses of metronidazole (Flagenase 400 pediatrico, Laboratorios Liomont, Cuajimalpa, Mexico 05000) at 4.0 ml/kg were administered in food items 10–14 days apart.

A fiberglass exhibit measuring 122 cm tall x 107 cm wide x 81 cm deep was used to house a pair of snakes. Light and heat were provided by one 150 W spot light and two 135 W flood lights placed directly on the screen wire that covers the top of the exhibit. This created basking spots of 29.4–35.0°C. In addition, a 61 cm double fluorescent light fixture equipped with Duro-Test Vita-Lites was used for supplemental light and for the benefit of the plants. A fiberglass rock water bowl was provided at all times. An *Elaeagnus* shrub was planted in the right rear corner of the exhibit and covered ca. 70% of the enclosure at the time of this writing. Dried grasses and rocks were arranged on the exhibit floor for aesthetic value.

Beginning in October 1994, the photoperiod was gradually, over a period of three months, shortened to 8 h of light and 16 h of dark. Likewise,the ambient temperature was slowly decreased to a daytime high of 22.2°C and to a nighttime low of 16.7°C. In mid-February, the photoperiod was gradually increased to 14 h of light and 10 h of dark, while the ambient temperature was increased to a daytime high of 25.6°C and nighttime low of 22.2°C. The St. Louis Zoo reported a photoperiod ranging from 9 h of light in November to 13 h of light in July with a year-round, daytime ambient temperature of 25.6–26.7°C (nighttime low of 23.9°C in the summer and 22.2–23.3°C in winter) (Ettling, pers. comm.). Shine et. al. (1996) describe both sexes of *T. capensis* as having highly seasonal reproductive cycles; consequently, some method of cycling may be necessary to induce reproduction in captivity.

In March 1994, a male was placed on exhibit followed by the female in December of the same year. On 3 May 1995, courtship behavior was observed. This behavior was typified by the male crawling over the female while frequently flicking its tongue and jerking its head. Copulation was noted on 15 May 1995. During the courtship process, the male ceased to feed while the female's appetite markedly increased. Her diet was doubled to two mice per week. By late June, the female's girth noticeably increased. On 6 July 1995, the female shed. The snake was removed from exhibit and placed in an aquarium measuring 61.0 x 40.6 x 30.5 cm. Several branches and a plant were added. A nest box was assembled by placing damp sphagnum moss in a plastic shoe box measuring 25 cm x 40 cm. It was then covered by a similarly sized shoe box that had an access hole cut in it. During this time (post-shed to oviposition), the female was offered food but refused. Over the next several days, the snake entered the nest box on many occasions. On 16 July 1995, eleven fertile eggs were laid underneath the moss within the nest box. As the entire clutch of eggs was adherent, individual egg lengths and weights were not available (Table 1). The female was returned to the exhibit on 19 July 1995. Copulation was again observed on 5 September 1995. On 13 October 1995, a clutch of four eggs was laid, three of which were fertile. The infertile egg (yellow, smooth, and shiny) was discarded.

The following year the snakes were cycled by manipulating the temperature and photoperiod as discussed previously. On 9 May and 20 May 1996, copulation was observed. On 12 June 1996, the female shed. On 21 June 1996, a clutch of nine fertile eggs was laid. Although the female remained off exhibit, a second clutch of eleven fertile eggs was produced on 4 September 1996. As a nest box was not provided, the snake laid the eggs under the newspaper substrate.

At the St. Louis Zoo, one female *T. c. oatesii* laid a clutch of seven eggs on 14 May 1997, while a second female laid a clutch of five eggs on 13 July 1997 (Ettling, pers. comm.) (Table 1). Both breedings represent second generation reproduction. One female was 1 yr 7 mo 16 d old at the time of oviposition, while the other female was 1 yr 9 mo 13 d. The males were the same age as the females. Haagner (1995) reported a clutch of 10 eggs laid by a wild-caught *T. c. capensis* (Table 1).

Incubation medium consisted of two parts vermiculite to one part water by weight. This was placed in a covered glass jar (0.5 liter). A variety of temperatures were used to incubate the eggs; however, no correlation seemed to exist between incubation temperature and hatchling size (Table 1).

Initially, the hatchling *Thelotornis* were placed in aquaria measuring 50.8 x 30.5 x 25.4 cm with two or three snakes per cage. Within three weeks, an attempt at cannibalism was observed; consequently, the snakes were separated and housed individually. Each enclosure contained a water bowl, several branches, and a small plant. Paper towels and newspaper were used as substrates

The hatchlings were offered food after ecdysis occurred (usually within ten days after hatching). Like the adults, they readily accepted *Anolis* lizards. Usually, one or two snakes per clutch immediately accepted live newborn mice. Tease feeding with newborn mice proved to be a successful strategy. For the remaining snakes, the same methods used to entice the adults to feed on mice were implemented with the hatchlings. All hatchlings were feeding on unscented newborn mice within three months.

Because *Thelotornis* are not widely held, a lack of captive husbandry and reproductive parameters exists. Their reputation as poor captives can be summed up by Patterson (1987), who stated that perhaps only one out of every 30–40 twig snakes settles into captivity and most do not adapt to an alternative diet. However, the techniques implemented at the Riverbanks Zoo illustrate that *T. c. oatesii* will thrive and reproduce in captivity and can be trained to accept a rodent diet.

Acknowledgments.—I thank Scott Pfaff for the opportunity to work with these outstanding serpents and for his helpful comments on the text, and Jeff Ettling and his staff at the St. Louis Zoological Park for their contribution of valuable data.

NATURAL HISTORY NOTES

Instructions for contributors to Natural History Notes appear in Volume 29, Number 1 (March 1998).

CAUDATA

AMBYSTOMA CALIFORNIENSE (California Tiger Salamander). **SURVEY TECHNIQUE.** *Ambystoma californiense* is generally fossorial during the nonbreeding season and little is known of its underground habits. A new technique for locating and observing these salamanders underground is described herein. During Fall 1995, pipeline construction was scheduled to cross known *A. californiense* habitat 10 km SW of Santa Maria, California, USA. In an attempt to "clear" the pipeline right-of-way prior to construction, a fiber optic scope was utilized to locate *A. californiense* underground. The scope was an Olympus IF11D4-30 with a 3 m probe that could be powered by a car battery or with a portable battery. With this scope I was able to locate and observe a number of juvenile *A. californiense* within California ground squirrel (*Spermophilus beecheyi*) and Botta's pocket gopher (*Thomomys bottae*) burrows. All salamanders were located at depths of 1.3–2.1 m (length of the probe, not depth under the surface). These depths documented only the first salamander observed in each burrow. Within one burrow, a ground squirrel was observed in a bed of dried grass and upon its retreat from the probe, three juvenile *A. californiense* were observed in the grass below and to the side of the ground squirrel's location. *Ambystoma californiense* observed were generally active (possibly due to the bright scope light) and were often located along the sides of the burrows.

The scope was effective, although somewhat limited, in locating *A. californiense*. It was able to negotiate the 90° turns of the rodent burrows; however, two or more sharp turns would cause it to jam in the burrows. The directional head was helpful in guiding the probe around turns, although many burrows were too complex or too deep for the 3 m probe. I was able to verify presence, but not absence, of *A. californiense* within a certain burrow system.

Upon identification of several burrows containing *A. californiense*, an attempt was made to entice them above ground for capture and possible relocation. These burrow systems were encircled with silt fencing, pitfall traps were installed inside the fence, and a water truck was brought in to apply water to the enclosed areas. The enclosures (20 m^2) were saturated twice a day for two days using a total of 18,925 L of water. One juvenile *A. californiense* was caught in a pit-fall trap the morning after the second day of watering. Even with this limited success, the experiment was discontinued due to the size of the habitat to be crossed and the water required to simulate rain.

I thank Tom Olson for reviewing this manuscript and for the loan of and training on the fiber optic scope.

Submitted by **VINCENT J. SEMONSEN**, Essex Environmental, 1810 Sunset Avenue, Santa Barbara, California 93101, USA.

ANURA

BUFO BOREAS (Western Toad). **MORTALITY.** While conducting a study of the movements and habitat use of adult *Bufo boreas* in the Targhee National Forest in southeastern Idaho, USA, I observed the mortality of numerous recently metamorphosed toadlets resulting from trampling by domestic sheep. My study area was centered on a 15 ha temporary pond, located within a pine/spruce forest. This area was within a grazing allotment that was grazed by sheep for about a week as they were driven towards private land. The pond is an important breeding site for *B. boreas* but usually dries by late July or early August. Over 20 pairs of *B. boreas* bred there in 1993 and 1995, but the only successful reproduction was in 1995. Because of the prolonged drought in the area, 1995 may have been the first successful reproduction since about 1986. By late July 1995, a large number (1,000's) of newly metamorphosed toadlets had concentrated at the shallow west shore; by 1 August the pond had dried.

On 4 August 1995, 500–1000 sheep were herded to within 150 m of the dried pond. At 0700 h on 5 August, I arrived at the pond and discovered the sheep were being driven into the dried pond from the west shore, through the concentration of toadlets and towards the habitat frequented by adult toads. After an hour the sheep were driven out of the pond through the opposite shore. As a result, an extensive area of riparian vegetation was completely flattened, and the majority of the toadlets were dead or dying. Hundreds were trampled by the sheep and by the end of the day hundreds more had desiccated. I checked three telemetered adults toads that were located in another part of the pond that was trampled by sheep and found they had escaped injury, apparently by hiding under logs or in rodent burrows.

BUFO PARACNEMIS (Sapo-boi). **DEATH FEIGNING.** In tropical anurans, death feigning or thanatosis (Edmunds 1974. Defense in Animals. Longman, New York, 357 pp.) is documented in hylids (Sazima 1974. J. Herpetol. 8:376–377; Duellman and Trueb 1986. Biology of Amphibians. McGraw-Hill, New York. 670 pp.; Azevedo-Ramos 1995. Rev. Bras. Biol. 55:45–47). In the genus *Bufo*, there is a brief report of such behavior in *B. ictericus* in southeastern Brazil (Haddad and Sazima 1992. *In* L. P. C. Morellato [ed.]. História Natural da Serra do Japi: Ecologia e Preservação de uma Área Florestal no Sudeste do Brasil, pp. 188–211. Editoria da Unicamp/FAPESP, Campinas). Herein we report death feigning in *B. paracnemis*, a large toad widely distributed in South America (Frost 1985. Amphibian Species of the World. Allen Press, Lawrence, Kansas. 732 pp.).

On 24 February 1997, we found seven *B. paracnemis* (61–106 mm SVL; 16–115 g) resting under a board in a deforested area near the Mucuri River, Municipality of Mucuri, State of Bahia, eastern Brazil. When handled, the two smaller specimens (61, 65 mm SVL; 16, 22.7 g) exhibited death feigning. The smallest specimen adopted a typical motionless posture, with its limbs close to the body and eyes closed (Fig. 1) for 15–20 min. This behavior was preceded by secondary defensive mechanisms, observed in all specimens, including attempted escape, inflation of lungs, and emptying of the bladder. Although the function of death feigning is not well understood, it has been related to the avoidance of dead prey by certain predators or to the minimization of prey injury when seized by a predator. (Sazima, *op. cit.*; Azevedo-Ramos, *op. cit.*). Voucher specimens are deposited in the Coleção

Zoológica da Universidade Federal do Espírito Santo (ZUFES 140349-354) and the Museu Nacional do Rio de Janeiro (MNRJ 18913).

FIG. 1. Juvenile *Bufo paracnemis* feigning death.

We thank Ivan Sazima and José Perezx Pombal, Jr. for reading this manuscript and for identification of the toad. CZ thanks the PICDT/CAPES (fellowships grant) and RLT the CNPq (grant 302657/87-8). We dedicate this note in memory of Adão José Cardoso for his contribution to the knowledge of Brazilian anurans.

Submitted by **CLAUDIO ZAMPROGNO, MARIA DAS GRAÇAS F. ZAMPROGNO**, and **ROGÉRIO L. TEIXEIRA**, Departamento de Biologia, Universidade Federal do Espírito Santo, 29040-090 Vitória, Espírito Santo, Brazil.

ELEUTHERODACTYLUS SCHWARTZI (NCN). **REPRODUCTION.** On 10 October 1996, we observed five nests of the terrestrial frog *Eleutherodactylus schwartzi* on Great Dog Island, British Virgin Islands, West Indies. To our knowledge, this is the first report of nests of this species, which is endemic to the British Virgin Islands.

The nests were within separate bromeliads located in a patch of ground bromeliads (*Hohenbergia antillana*) that were ca. 16 x 13 m. Based on locations of advertisement calls of males after dark, the distribution of *E. schwartzi* on the island was almost exclusively confined to this patch. Rain had fallen on the days before our initial visit, and the habitat was moist. All nests were within an area ca. 3 m in radius. Each globular egg mass was attached to the inner surface of a leaf near the center of the bromeliad and towards its base. The center was moist, but there was no standing water. One nest was within an arboreal bromeliad (*Tillandsia* sp.), whereas the remaining nests were within bromeliads on the ground. Four nests contained a single clutch, whereas one contained two clutches. The eggs in three clutches were white and firm and were presumably newly-laid, whereas the others were discolored and larger. Movement and the presence of eyespots in the embryos within these larger eggs indicated that they were further along in development.

A male frog was in attendance at each nest and was either hunched over the eggs, or near the center of the bromeliad facing the eggs. In one case, a male appeared from the center of the bromeliad and approached the eggs when we held back the leaf for photography. One male (in Nest 2 below) was attending two egg masses located within a few centimeters from each other. We observed this frog switching positions from covering one egg mass to the other. Male parental care has not previously been reported for *E. schwartzi*.

The details of the nests recorded on 10 October were as follows: *Nest 1*: 12 eggs, white; egg diam 4.6–4.9 mm; located at a height of 180 cm within *Tillandsia* sp. in a tree. This nest together with the attending male, was transported to the laboratory on Guana Island. All eggs, which were kept at 26–28°C became infested with mold with the exception of one egg that hatched on 21 October. Both the hatchling and the male were deposited in the collection at the Museum of Comparative Zoology, Cambridge, Massachusetts (MCZ 125947–948). *Nest 2*: Egg mass 1 with 13 eggs, white; egg diam 4.4–4.9 mm; Egg mass 2 with 5 eggs, discolored; movement within eggs; egg diam 5.5–8.0 mm; located 40 cm from ground within *H. antillana*. *Nest 3*: 5 eggs, discolored; movement within eggs; egg diam 5.4–6.1 mm; located 36 cm from ground within *H. antillana*. *Nest 4*: 10 eggs, white; egg diam 5.0–5.5 mm; located 30 cm from ground within *H. antillana*. *Nest 5*: 10 eggs, discolored; movement within eggs; egg diam 8.4–8.8 mm; located 25 cm from ground within *H. antillana*.

FIG. 1. Male *Eleutherodactylus schwartzi* attending two egg masses within a bromeliad.

By 16 October, all the older egg masses in Nests 2, 3, and 5 had disappeared and presumably had hatched. In Nest 4, a frog was hunched over the eggs, which had been reduced from 10 to 6. The eggs were now discolored and appeared close to hatching. Five of the 13 eggs on the newer egg mass in Nest 2 were desiccated on the leaf. There was no trace of the other eggs or the older egg mass. An adult frog was at the base of the leaf. Folding back the leaf during our initial visit could have changed the microclimate and resulted in the eggs drying. Very little rain had fallen in the days preceding our second visit. Gad Perry and Kate LeVetring provided valuable assistance in locating the frogs and nests.

PHYSALAEMUS NATTERERI (NCN). **PREDATION.** On 20 August 1996 a crab-eating fox (*Cerdocyon thous*) was collected on the highway between Caldas Novas and Ipameri (17°42'S, 48°32'W), State of Goiás, Brazil. Stomach analysis revealed *Physalaemus nattereri*, a small, nocturnal leptodactylid known for its defensive deimatic strategy of suddenly exposing the large ocelli on its back (Sazima and Caramaschi 1986. Rev. Biol. [Lisb.] 13:91–101) and for its ability to secrete holocrine substances from its inguinal glands (Vizotto 1964. Ci. e Cult. 16:168–169).

The present record obtained from a wild predator confirms the observations of Sazima (1973. Ci. e Cult. 25[supl.]:390), who observed predation of *P. nattereri* by captive representatives of all terrestrial vertebrates classes, except the burrowing owl (*Athene cunicularia*), suggesting that the deimatic behavior shown by *P. nattereri* of raising the posterior part of the body and hiding the anterior and ventral parts has a more defensive than inhibitory effect on a potential predator.

The partially digested specimen of *P. nattereri* was identified by José Perez Pombal Jr., and is deposited in the mammal collection of Museu Nacional (Universidade do Rio de Janeiro) as the stomach content of MN 37658.

TESTUDINES

CLEMMYS MARMORATA PALLIDA (Southwestern Pond Turtle). **COPROPHAGY.** Ernst et al. (1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington, D.C., 578 pp.) reported intra- and interspecific coprophagy in North American tortoises (*Gopherus* spp.). In addition, red-eared sliders (*Trachemys scripta elegans*) are known to eat pig feces (D. Holland, pers. comm.). Western pond turtles (*Clemmys marmorata*) feed on a wide range of prey items (primarily aquatic invertebrates) and scavenge extensively (Bury 1986. J. Herpetol. 20:515–521). Here we present the first report of coprophagy in the southwestern pond turtle (*Clemmys marmorata pallida*).

On 3 July 1996 (1135 h), the first author observed a juvenile *C. m. pallida* (63.9 mm CL, 43 g) feeding on a coyote (*Canis latrans*) scat in a stream in the Chino Hills State Park, San Bernardino County, California, USA. The scat (6.0 g) was analyzed and found to contain mammal bones and hair, arthropod parts, plant material and seeds, and unknown waste matter. It is unclear what nutritional benefit the turtle obtained from eating the feces.

We thank Stephen H. Bryant, Curtis Clark, W. David Edmonds, and Dan C. Holland, for their comments and help with identification of arthropod and plant components.

CLEMMYS MUHLENBERGII (Bog Turtle). **PARASITES.** Although leeches of the genus *Placobdella* parasitize many species of freshwater turtles, there are no published records involving *Clemmys muhlenbergii* (Moser 1995. Texas J. Sci. 47:71–74; Watermolen 1996. J. Fresh. Ecol. 11:211–217). Such data are needed since leeches are known vectors of turtle endoparasites such as trypanosomes (Woo 1969. Can. J. Zool. 47:1139–1151) and haemogregarines (Siddall and Desser 1992. Can. J. Zool. 70:123–128).

Between 10 June and 5 September 1996, 23 bog turtles were captured 107 times from four spring-fed, wet meadows in Floyd County, Virginia, USA, and examined for leeches. Upon initial capture, 7 male and 5 female turtles (mean ± SD; [range]: CL = 92.64 ± 3.71 mm [87.4–99.07 mm]; mass = 121.08 ± 14.16 g [98–145 g]) were parasitized by a total of 20 leeches. Leech prevalence was 52.2% and mean intensity was 1.67 ± 1.53 (range = 1–8). The parasites were distributed on the turtles as follows: carapace = 60%; plastron = 20%; posterior limbs = 15%; tail = 5%. Because all leeches were removed from each turtle, it was possible to document recolonization. An adult female *C. muhlenbergii* captured on 1, 11, 15 July, and 17 August, 1996 was parasitized by 8, 5, 1, and 2 leeches, respectively. A male captured on 10 June, 15 and 18 July, and 1 August, 1996 had 1, 3, 3, and 1 leeches. Another male captured on 19 June and 16 July, 1996 had a single leech on both occasions. When identification was possible (23 of 36 cases), leeches were identified as *Placobdella multilineata*. Thirty-three leeches were deposited into the Royal Ontario Museum's invertebrate collection (ROM IZI 4363).

Because *P. multilineata* is known to parasitize several species of turtles (Forrester and Sawyer 1974. J. Parasitol. 60:673; Sawyer and Shelley 1976. J. Nat. Hist. 10:65–97) that are known hosts of haemogregarines (Wang and Hopkins 1965. J. Parasitol. 51:682–683; Patterson and Desser 1976. J. Protozool. 23:294-301; McAuliffe 1977. J. Parasitol. 63:580–581), and because *P. multilineata* is a known vector of alligator haemogregarines (Khan et al. 1980. J. Parasitol. 66:324–328), future research should investigate blood parasites in *C. muhlenbergii*.

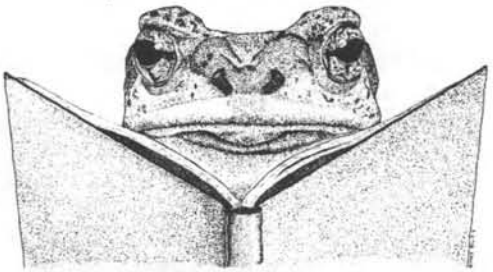
We thank Melody A. Kirkendall and C. Shay Garriock for assistance in the field, Don Stacey of the Invertebrate Zoology Department of the Royal Ontario Museum for confirming leech identifications, and Carola A. Haas and Joseph C. Mitchell for support and guidance. This research was supported by the U.S. Fish and Wildlife Service, Virginia Department of Game and Inland Fisheries, and the Wildlife Conservation Society.

Submitted by **RAYMOND A. SAUMURE**, Department of Natural Resource Sciences, McGill University, 21111 Lakeshore Road, Ste-Anne-de-Bellevue, Québec, H9X 3V9, Canada, and **SHAWN L. CARTER**, Department of Fisheries and Wildlife, Virginia Polytechnic Institute and State University, 100 Cheatham Hall, Blacksburg, Virginia, 24061-0321, USA.

LACERTILIA

CNEMIDOPHORUS (Whiptail Lizards). **DIET.** During 1993 field work in the Mexican state of Morelos, we collected representatives of three species of *Cnemidophorus*. Although species of *Cnemidophorus* are known to feed primarily on small insects, they occasionally prey on other reptiles. Nothing is known, however, about the sizes and kinds of reptiles consumed.

A female *C. deppei infernalis* (SVL 80 mm, tail 167 mm, mass 12 g) was collected on 14 February 1993 at Las Piedras (18°40'N, 98°59'W), in the municipality of Ayala, Morelos, México, at 1020 m elevation, in dry, tropical forest habitat. Its stomach contained a small snake, *Leptotyphlops maximus* (SVL 116 mm, mass 0.51 g).



On 13 June 1993 we collected a male *Cnemidophorus sacki gigas* (SVL 129 mm, tail 163 mm, mass 65.0 g) at El Caracol

DAS TIERREICH / THE ANIMAL KINGDOM

A CHARACTERIZATION AND COMPILATION OF ALL CURRENT ANIMAL GROUPS

Edited by Maximilian Fischer and Heinz Wermuth

Part 112:

Chamaeleonidae

Wolfgang Böhme and Charles J. Klaver

1997 • xvi + 88 pages • Hardcover $132.00 • ISBN 3-11-015187-1

A complete overview of all known chameleon species and subspecies including all synonyms, type localities, type specimens and geographical distribution. In addition, detailed comments are given on problems concerning nomenclature, classification, types, and distribution.

(18°53'N, 99°00'W), in the municipality of Yautepec (1031 m elevation) in tropical dry forest. Its stomach contained six eggs of a conspecific, possibly a full clutch (mean egg mass 0.35 g ± 0.23 (0.05–0.61 g, mean length 14.5 ± 0.56 mm (14.0–15.4 mm), mean width 11.2 ± 0.7 mm (10.0–11.7 mm).

Finally, an adult male *Cnemidophorus costatus costatus* (SVL 97.0 mm, mass 27.5 g) was collected on 30 July 1993 in the same area of El Caracol. Its stomach contained the remains of a snake, *Masticophis mentovarius* (SVL 140 mm, mass 1.38 g).

These data suggest that *Cnemidophorus* in this area not only eat small invertebrates, but also reptiles and the eggs of lizards. Lizards of the genus *Cnemidophorus* are known to be an active foragers, spending considerable time searching for prey on the ground. These new data confirm their foraging habits, as the prey eaten were found in leaf litter, and the *Cnemidophorus* eggs consumed are known to be deposited on the ground among dry foliage.

We thank L. A. Fitzgerald for his comments on this manuscript, and R. J. Torres for his help in the field.

CTENOSAURA PECTINATA (Brown Iguana) **DIET**. Reports from different locations throughout its range indicate that *C. pectinata* predominantly feeds on leaves, fruits, and insects, and to a lesser extent on nestling birds and mice (Evans 1951. Amer. Mus. Novit. 1493:1–26; Fitch et al. 1971. Southwest. Nat. 15:397–399; Alvarez del Toro 1972. Los Reptiles de Chiapas. Gob. del Edo. de Chiapas. México). Its diet on Isla Isabel, México (a 98.3 ha island 28 km off the coast of Nayarit, 21°52'N, 105°54'W), is known only from unpublished anecdotal records, and includes the new leaves and fruits of "ruache" trees (*Crataeva tapia*) during the rainy season, sooty tern (*Sterna fuscata*) and brown pelican (*Pelecanus occidentalis*) nestlings, and one report of a 3 cm^3 piece of fish. Herein we report the stomach contents of 10 *C. pectinata* captured on this island.

Lizards were captured by noosing in March 1992, during the dry season, when ruache trees do not produce leaves or fruits. The only new leaves available are those of herbaceous plants thriving on dew that accumulates overnight. At this time of year, five of the nine seabird species inhabiting the island were breeding. Six lizards were captured between 0900 and 1300 h in the northeastern part of the island, in a ruache forest that is also a major nesting site of blue-footed boobies (*Sula nebouxii*). Four additional lizards were captured in adjacent grassland.

Lizards were measured (SVL) and weighed. Eight males measured 29–36 cm SVL (33 ± 1.9 cm) and weighed 750–1650 g (1248 ± 254 g); two females measured 19–23.4 cm (21.2 ± 2.2 cm) and weighed 27–34 g (34.1 ± 3.7 g). Stomach contents were flushed out with water, and preserved in 70% ethanol. Stomachs of nine of the ten lizards contained food items. Five males and both females had *Portulaca oleracea* leaves in their stomachs. The stomachs of two other males contained animal tissue and bone fragments that were probably the remains of nestling birds, based on their size and porosity. These data and those coming from unpublished observations suggest that *C. pectinata* living in the northern part of Isla Isabel are food generalists, and opportunistically feed on nestling seabirds.

Submitted by **CRISTINA RODRIGUEZ-JUAREZ** and **JOSE LUIS OSORNO CEPEDA**, Instituto de Ecología, Universidad Nacional Autónoma de México, A.P. 70-275, 04510. D.F., México.

EUMECES LATICEPS (Broadhead Skink). **NATURAL NESTS**. Observations on natural nests in *Eumeces laticeps* suggest that eggs are laid from late June through July, that clutch size is 6–20, and that eggs are 13.0–19.8 mm long and 9.0–14.8 mm wide (Martof 1956. Herpetologica 12:111–114; Mount 1975. The Reptiles and Amphibians of Alabama. Alabama Agri. Exp. Sta. Auburn, Alabama. 347 pp.; Palmer and Braswell 1995. Reptiles of North Carolina. Univ. North Carolina Press, Chapel Hill. 412 pp.; Smith 1946. Handbook of Lizards. Cornell Univ. Press, Ithaca, New York. 557 pp.). Martof (*op. cit.*), however, mentioned one nest found in mid-September from the Blue Ridge of Georgia. Here we add to this observation by presenting information on two other clutches from Georgia.

On 2 July 1997 two *E. laticeps* were found in Seminole County, Georgia, USA, brooding 15 and 16 eggs, respectively. Both specimens were situated in oval cavities beneath a single sheet of roofing tin that was on the ground. The nests were less than one meter apart, and appeared very similar to a nest described by Martof (*op. cit.*) from Thomas County, Georgia. During discovery of the first nest, a nearby colony of imported fire ants (*Solenopsis invicta*) was disturbed. Several ants reached the nearest *Eumeces* nesting chamber and were quickly consumed by the attending female. No ants were observed to reach the second nest.

Both clutches and the attending females were collected. Eggs from both clutches appeared to be of similar size and shape, and no damage to any of the eggs was noted. Several days later, it was discovered that one of the eggs from the clutch of 15 was ruptured, and most of the contents lost. Closer examination of the container housing this clutch revealed a single large worker fire ant, although it is not known if the egg was damaged by this ant, or during transit.

Mean length for the 14 remaining eggs in this clutch was 18.06 ± 0.53 mm (range 17.40–19.13 mm); width 13.49 ±0.43 mm (range 12.75–14.10 mm); and mass 1.84 ± 0.14 g , (range 1.6–2.0 g). The attending female (SOCM 0287) measured 115.0 mm SVL, 238.8 mm TL, and 26.2 g mass. Mean egg length in the second clutch was 18.30 ± 0.87 mm (range 16.78–19.87 mm); width 12.93 ± 0.49 mm (range 12.20–13.95 mm); mass was 1.68 ± 0.20 g (range 1.3–2.0 g). The attending female of this clutch (SOCM 0288) measured 111.7 mm, 271.7 mm TL, and weighed 26.9 g.

The size of eggs in these two clutches corresponds with the upper end of known ranges for natural nests. Smith (*op. cit.*) indicated that eggs of this species increase in size as they near hatching. Thus it is possible that both clutches discussed above were near hatching.

Submitted by **ROBERT A. MOULIS** and **GERALD K. WILLIAMSON**, Savannah-Ogeechee Canal Museum and Nature Center, 681 Fort Argyle Road, Savannah, Georgia 31419-9239, USA.

PHRYNOSOMA PLATYRHINOS (Desert Horned Lizard). **PREDATION**. Known predators of horned lizards (genus *Phrynosoma)* were recently summarized (Duncan et al. 1994. Herpetol. Rev. 25:68) but no invertebrates were included. We observed apparent predatory behavior on *P. platyrhinos* by a scorpion during a nocturnal survey of the East Pinta Sands, Cabeza Prieta National Wildlife Refuge, Arizona, USA. The area is a sparsely-vegetated sand sheet within the Lower Colorado River Valley Subdivision, Sonoran Desertscrub community (Turner and Brown 1982. *In* D. E. Brown, ed., Biotic Communities of the American Southwest—United States and Mexico, pp. 181–221. Desert Plants 4). At 2120 h on 6 May 1997, we discovered an adult *Hadrurus arizonensis* (Arizona giant hairy scorpion) carrying on its back a juvenile *P. platyrhinos* in an upside-down position (Fig. 1). The scorpion had a firm grasp with its chelicerae on the lizard's dorsal skin at the base of the tail. The lizard's left rear leg was held in the scorpion's left pedipalp, and the right rear leg was supported by its right pedipalp, so that the lizard's head rested on the base of the scorpion's tail. The lizard was still alive, and managed to break free after we had been observing the pair for ca. 30 min. We held the lizard overnight and released it, apparently unharmed, the following morning. The scorpion had a body (carapace + mesosoma) length of 44 mm, tail (metasome + telson, excluding recurved portion of telson) 51 mm, and mass 8.3 g. Lizard SVL was 52 mm, tail 26 mm, mass 6.4 g.

Although horned lizards commonly spend summer nights burrowed into the ground (Heath 1965. Univ. California Publ. Zool. 64:97–136), nocturnal activity by *P. platyrhinos* has been described (Pianka and Parker 1975. Copeia 1975:141–162). This potentially puts it into contact with *H. arizonensis*, which is most active in the first hour after sunset (Fox 1975. Unpubl. Ph.D. dissertation, Arizona State Univ., Tempe). Laboratory tests found that while stinging was a common behavior in capturing large prey, *H. arizonensis* venom had no lethal or immobilizing effect on several lizard and mouse species. Envenomation, however, was not necessary for successful ingestion of vertebrate prey so long as the scorpion could immobilize its prey with its pedipalps (Hadley and Williams 1968. Ecology 49:726–734). *Hadrurus arizonensis* has been found in densities up to 0.5/m^2 in the Colorado Desert (Williams 1980. Occ. Pap. California Acad. Sci. 135:1–127), and thus may be a significant predator on horned lizards in shared habitat.

We thank George Bradley for assistance with scorpion description and literature.

Submitted by **DALE S. TURNER**, School of Renewable Natural Resources, University of Arizona, Tucson, Arizona 85721, USA, and **JIM RORABAUGH**, Arizona Ecological Services Office, U.S. Fish and Wildlife Service, 2321 West Royal Palm Road #103, Phoenix, Arizona 85021, USA.

PTYODACTYLUS OUDRII (NCN). **PARENTAL CARE.** Parental care through egg-attendance is a common behavior in some vertebrates but is relatively rare in reptiles. Reported examples in reptiles are indeed very primitive and include a) the active manipulation of eggs soon after oviposition to locate them at favorable places, b) parents remaining in the vicinity of the eggs after oviposition, returning to them regularly, c) a more complex behavior where the parent(s) remain coiled around the eggs to facilitate embryonic development by thermogenesis, d) active defense of clutches against potential predators and finally, more rarely, e) the care of newly hatched juveniles (cf. Shine 1988. *In:* C. Gans and R. B. Huey, eds., Biology of the Reptilia. Defense and Life History. Vol. 16, Ecology B. A. R. Liss Inc. New York, pp. 275–329). All these behaviors are likely to increase the survival of offspring.

The manipulation of eggs after oviposition is rare in Squamata and so far, has never been reported in geckos. The only reported exception refers to the relocation of eggs soon after oviposition in the Moorish gecko, *Tarentola mauritanica*, to settle them at suitable places (Nettman and Rykena 1979. Salamandra 15:53–57). Here, we describe a noteworthy example of parental care by manipulation, body rubbing of the eggs, and egg licking in *Ptyodactylus oudrii*. To our knowledge, this is the first time that this complex type of parental care has been reported in reptiles.

Ptyodactylus oudrii is an insectivorous, small sized (adult SVL 50 mm, mass 3.4–7 g) gecko found in mountain areas of Tunisia, Algeria, and Morocco (Heimes 1987. Salamandra 23:212–235; Le Berre 1989. Fauna du Sahara I. Poisson-Amphibies Reptiles. Lechevalier-R. Chabaud, Paris, 352 pp.) in very harsh, arid zones throughout its distribution. The species lives in small colonies (mean = 10 individuals, range 4–20) on the vertical and overhead walls of caves and culverts under roads (García-Márquez et al. 1996. Bol. Asoc. Herpetol. Esp. 7:28–30). The presence of a morphological adaptation in their limbs (a "plumage" structure instead of claws) allows them to walk on these surfaces. As in other species of *Ptyodactylus*, this gecko performs communal oviposition, fixing the clutches directly onto the overhead or lateral walls of the caves. Clutch size is often two, with calcified, spherical, white eggs, 12–14 mm diameter. In captivity, *P. oudrii* completes its reproductive cycle in 40 days, laying multiple clutches per year (unpubl. data).

A total of 31 *P. oudrii* (15 males and 16 females) were captured near Ouarzazate (30°55'N, 6°51'W, S Morocco) in May 1990 and transported by car to Sevilla (southern Spain) for detailed observations of parental care. The geckos were kept in communal cages (3 x 3 x 1 m) under lab conditions, at ambient temperatures (28–31°C) with a 12:12 h light regime. The walls of the cages consisted of a mesh grid (0.3 cm width) with a cover allowing the geckos to walk on overhanging surfaces. A glass terrarium was also used for detailed observations. Both the cage and the terrarium were provided with a 10 cm sand substrate and were watered regularly to increase ambient humidity. Food (crickets, cockroaches, and mealworms) and water were provided *ad libitum*. The geckos completed several reproductive cycles in captivity, showing no apparent stress.

A unique nesting site was observed in each cage. The clutches hung from the ceilings of each cage, or, less often, on the vertical walls of the terraria, typical behavior observed in free-ranging

geckos (see García-Márquez et al. in press *op. cit.*). Clutch size was consistently two with different clutches easily distinguishable. The remains of previous nesting attempts (e.g., shells, carcasses) were also observed at each nesting place. Parental care observed included egg cleaning by continuous body rubbing and egg-licking with the tongue. Geckos moved freely within the clutches. All geckos available in the colony (both sexes, all age-classes) performed active manipulation of eggs during incubation, returning regularly. Each individual attended not only to its own clutch, but to others, an example of communal parental care. Eggs were not moved from their original oviposition location. Often, several geckos remained in the vicinity of a clutch after oviposition, returning to it regularly, thus keeping the nesting site attended by at least one individual at all times.

The manipulation of eggs by *P. oudrii* may represent an active defense against pathogens or fungal attacks (e.g., Forester 1979. Copeia 1979:332–341; Shine 1988, *op. cit.*). Other potential sources of mortality such as predation or egg desiccation might also be reduced. According to Noble and Mason (1933 in Shine 1988, *op. cit.*), parental care in reptiles may have evolved more rapidly in non-burrowing species where appropriate limbs to excavate a nest are lacking. Also, parental care is more likely to occur in harsh, highly variable environments (Huntingford 1984. The Study of Animal Behaviour. Chapman and Hall, 411 pp. Cornwall). Presumably, both factors may have played an important role in the evolution of this behavior in *P. oudrii*.

Animals were collected under a license from the Kingdom of Morocco (77-c/57-51-0).We thank Arturo González for raising the geckos in captivity. Comments provided by Claudia Keller and Carmen Díaz Paniagua improved this note. The work was financed by a DIGICYT project (PB# 94-0008) and a travel grant from Junta de Andalucía (group 4088).

SCELOPORUS UNDULATUS ELONGATUS (Northern Plateau Lizard). **MATING BEHAVIOR**. On 7 June 1997 at 0915 h, I encountered a male and female *Sceloporus undulatus elongatus* on a small rock outcrop at the confluence of Currant Creek and Flaming Gorge Reservoir, Sweetwater County, Wyoming, USA. The male was positioned diagonally across the back of the female so that his cloaca was to the right of hers. He was biting her neck just behind the left side of her head. The female attempted to remove the male from her back by lifting her hindlegs, one at a time, and scratching the male, while also moving around in a circle. The female then rolled onto her back, squirmed, and dislodged the male. Next, she stood parallel to the male and arched her back. Meanwhile, the male had righted himself. The female turned and faced the male while still in the arched posture, then charged him. The male retreated about 1 m up the rock outcrop. At this point, I captured both lizards (male: 57 mm SVL; 78 mm tail length; 5 g; female: 73 mm SVL; 86 mm tail; 14 g).

The behavior of the female could be interpreted in one of two ways. She may have been startled by me, thus triggering an escape attempt. Alternatively, this may have been rejection behavior in response to attempted copulation.

I thank Kristi L. Ashton and Alan de Queiroz for comments and suggestions on the manuscript.

SERPENTES

CHAMAELYCUS FASCIATUS (NCN). **DIET.** Few data are available on the feeding habits of *Chamaelycus fasciatus*, a small African colubrid snake reaching 350 mm total length (Doucet 1963. Les Serpents de la Côte d'Ivoire. Acta Tropica 20(3):201–340). Doucet (*op.cit.*:245) and Villiers (1975: 108. Les serpents de l'ouest africain. Intitiations et études africaines. No. II. 3ème édition, Université de Dakar, Institut Fondamental d'Afrique Noire. Les Nouvelles Editions Africaines, 195 pp.) reported it feeding on beetles and reptile eggs. An adult male (SVL 272 mm, tail 48 mm), collected in Congo, area of Loango, cataloged in the Paris Natural History Museum (MNHN 1973.1249) had a gerrhosaurid lizard, *Gerrhosaurus nigrolineatus* (SVL 62 mm, tail 135 mm), in its stomach (MNHN 1997.3339).

Submitted by **IVAN INEICH**, Museum National d'Histoire Naturelle, Laboratoire de Zoologie (Reptiles and Amphibiens), 25 rue Cuvier, F-75005 Paris, France; e-mail: Ineich@cimrs1.mnhn.fr.

CONOPHIS VITTATUS VITTATUS (Road Guarder, Guardo Camino). **CLUTCH SIZE.** On 17 March 1994 we collected a gravid *Conophis vittatus vittatus* from tropical dry forest at the Biological Field Station Chamela, Jalisco, México (19°30'N, 105°03'W). The snake was kept in captivity for two months after capture, with oviposition occurring on 21 May. The snake measured 620 mm SVL, tail 140 mm, mass 87.8 g before oviposition, and weighed 64.1 g after oviposition. Clutch size was 12 eggs and mean egg mass was 2.07 g (3.25–0.70 g). Mean egg length and width were 23.9 mm (18.5–29.5 mm) x 12.2 mm (9.5–14.3 mm); relative clutch mass (RCM) was 0.28 g. The RCM value is comparable to those for snakes of similar size (Seigel et al. 1986. Herpetologica 42:179–185; Ramírez-Bautista et al. 1995. Herpetol. Rev. 26:12–13).

We thank S. Monk for comments on the manuscript.

Submitted by **AURELIO RAMÍREZ-BAUTISTA** and **CARLOS BALDERAS- VALDIVIA**, Instituto de Biología, UNAM, Departamento de Zoología, A.P. 70-153, C. U., C. P. 04510, México 20, Distrito Federal, México.

BOTHROPS FONSECAI (Fonseca's Lancehead). **REPRODUCTION and SIZE.** Among the heavy-bodied pitvipers of the *Bothrops alternatus* group, *B. fonsecai* is the least known. This snake is found in montane areas of southeastern Brazil with mixed broadleaf and *Araucaria* pine forest (Campbell and Lamar 1989. The Venomous Reptiles of Latin America. Cornell Univ. Press, Ithaca, New York, 425 pp.). Here we provide data on reproduction and size for this species from two localities in São Paulo State.

A large (967 mm SVL, 112 mm tail length [TL]) female *B. fonsecai* was found DOR on 22 January 1993 in the Serra do Mar at Cunha (23°10'S, 44°55'W, 1120 m elevation), and deposited in the reptile collection of the Museu de História Natural, Universidade Estadual de Campinas (ZUEC 1562). The oviducts contained 14 fully-developed embryos, one of which was dam-

aged and not measured (SVL mean ± SD [range] in mm = 217.7 ± 5.9 [205–229]; TL = 36 ± 3.5 [27–42]).

The only reported measurements for *B. fonsecai* are that of the male holotype (Hoge and Belluomini 1959. Mem. Inst. Butantan 28:195–206). We measured 12 adult males that were collected in the Serra da Mantiqueira at Campos do Jordão (22°44'S, 45°35'W, 1540–1600 m elevation) and deposited at ZUEC (SVL = 661.6 ± 72 [550–755 mm]; TL = 104.1 ± 11.9 [80–120] mm). One female collected at this site measured 810 mm SVL and 100 mm TL. The related *Bothrops cotiara* averages 700–800 mm in total length and may reach 1000 mm (Campbell and Lamar, *op. cit.*).

We thank H. K. M. Corrêa and P. E. G. Coutinho for collecting the Cunha snake; O. Augusto, S. A. Chini, and C. R. C. Souza for help with fieldwork at Campos do Jordão; the Instituto Florestal (through M. J. Robim and J. L. Carvalho) for logistical support at Campos do Jordão and Cunha sites; and the CNPq for financial support.

ERYTHROLAMPRUS BIZONA (False Coral Snake). **DIET**. In the garden of a hotel in Curimagua, Estado Falcón, Venezuela, ca. 1150 m elevation, we found a false coral snake, *Erythrolamprus bizona* (CIEZAH 387), which subsequently regurgitated an adult *Ninia atrata* (CIEZAH 388). The *Ninia* was partially digested from the anal plate to the tail. Ophiophagy is well known in the genus *Erythrolamprus* but this is the first report of identified prey in Venezuela (Roze. 1970. Ciencia y Fantasia de las Serpientes de Venezuela. Editorial Fondo de Cultura Científica, Caracas. 160 pp.; Lancini and Kornacker. 1989. Die schlangen von Venezuela. Verlag Armitano Editores. Caracas. 381 pp.). The two specimens are deposited in the Herpetological Collection of the Centro de Investigaciones en Ecología y Zonas Áridas (CIEZAH), Universidad Francisco de Miranda, Coro, Venezuela.

Submitted by **ABRAHAM MIJARES-URRUTIA** and **ALEXIS ARENDS R.**, Centro de Investigaciones en Ecología y Zonas Áridas (CIEZA), Universidad Francisco de Miranda, Apartado 7506, Coro 4101-A, Venezuela; e-mail (AM): amijares@reacciun.ve and (AA): aarends@funflc.org.ve.

CROTAPHOPELTIS HOTAMBOEIA (White Lipped Snake). **SNAKEBITE**. The venom of *Crotaphopeltis hotamboeia* is thought to be harmless to humans (Spawls and Branch 1995. The Dangerous Snakes of Africa. Ralph Curtis Books, Sanibel Island, Florida. 192 pp.) yet fatal to small mammals and fowl (Frei 1910. Ztschr. F. Infektionskr., par Krankh U hyg. D. Haoustiere 3:211–217; FitzSimons 1912. The Snakes of South Africa; Their Venom and the Treatment of Snake-bite. T. Maskew Miller, Cape Town, South Africa. 547 pp.). At the Serena Lodge in Amboseli National Park, Kenya, at ca. 0130 h on 2 November 1989, a 22 year-old female was bitten while trying to rescue a *C. hotamboeia* (ca. 60 cm SVL) from a domestic cat. The bite was on the right index finger, and although the wounds were small, bleeding was immediate, profuse, and lasted several minutes. By dawn a large, medial hematoma was present. The hematoma was darkest at the wrist and extended up the right arm almost to the elbow. The hematoma and profuse bleeding are characteristic of a venom possessing anticoagulatory, hemorrhagic, spreading, and possibly hemolytic factors. The hematoma disappeared over the next several days, with no further ramifications. The snake was released in Amboseli on the day following the incident.

We thank Michael C. Cheptumo, Curator of the Snake Park at the National Museum of Kenya, Nairobi, who verified the identification of the snake from a photograph.

DIADOPHIS PUNCTATUS (Ringneck Snake). **PREDATION**. In his monograph on the ringneck snake (*Diadophis punctatus*), Fitch (1975. A Demographic Study of the Ringneck Snake, *Diadophis punctatus*, in Kansas. Misc. Publ. 62, Univ. Kansas Mus. Nat. Hist. 53 pp.) recorded three avian predators: the red-tailed hawk (*Buteo jamaicensis*), broad-winged hawk (*B. platypterus*), and great horned owl (*Bubo virginianus*). Here, we add a non-raptor, the American robin (*Turdus migratorius*), to this list of avian predators.

On 15 August 1996, DLH saw an adult robin capture a ringneck snake (ca. 20 cm TL). The encounter was observed through 7 X 42 binoculars and took place on the front lawn of DLH's Cincinnati, Ohio (USA) home. After pecking at the snake numerous times, the bird coiled the apparently dead snake in its bill and flew into the crown of a nearby tree. Later in the afternoon, SEH located a robin nest in the tree. The nest held two fully-grown young who fledged the following day.

The American robin previously has been reported as a predator of *Storeria dekayi* (Netting 1969. Wilson Bull. 81:471), *Thamnophis sauritus* (Eiserer 1976. The American Robin. Nelson Hall, Chicago, Illinois. 175 pp.), and *T. sirtalis* (Davis 1969. Wilson Bull. 81:470–471).

EUNECTES MURINUS (Green Anaconda) and ***PHRYNOPS GIBA*** (Gibba Turtle). **PREDATION.** On 7 January 1997, we observed a male *Eunectes murinus* constricting a *Phrynops giba* in the Bush Bush Wildlife Sanctuary, Trinidad, West Indies (Fig. 1). The anaconda had been there less than 24 h, as we had been to this location (10°02.273 N, 61°23.473 W; reading obtained from Trimble ScoutMaster GPS) the previous day. Our intrusion prompted the anaconda to release its hold, allowing the turtle to escape, apparently unharmed. The anaconda had a total body length of ca. 3.65 m; the turtle's carapace length was ca. 16 cm. Mole (1924. Proc. Zool. Soc. London [1]:235–278; cited in Murphy 1997. Amphibians and Reptiles of Trinidad and Tobago. Krieger Publ. Co., Malabar, Florida. 245 pp.) reported that turtles are included in the diet, but does not list species.We are unaware of other reports of anacondas attempting to eat turtles, and it is unclear whether this attempted predation would have been successful.

We thank Kim Phillips (Hiram College) for allowing us to accompany her to the Bush Bush Wildlife Sanctuary, and C. L.

Abercrombie (Wofford College) for assistance in identification of these species.

Submitted by **CARRIE ELVEY** and **KAREN NEWLON**, Department of Biology, Hiram College, Hiram, Ohio 44234, USA.

HIEROPHIS VIRIDIFLAVUS (Western Whip Snake). **NESTING HABITAT.** The western whip snake (*Hierophis viridiflavus*) is a large (up to 180 cm total length), oviparous colubrid that is widespread and extremely abundant over much of the Italian peninsula (Bruno and Maugeri 1990. Serpenti d'Italia e d'Europa, Editoriale G. Mondadori, Milano, 224 pp.). Little is known about the nesting habitat of this species. This note provides preliminary information on this issue.

On 16 May 1996, a female *H. viridiflavus* (86.0 cm SVL, 15.5 cm tail length) was captured in the internal pinewood (*Pinus pinea*) area of the Forest of Castel Fusano (ca. 20 km W of Rome). Palpation revealed that the snake was gravid. The snake was marked by ventral scale-clipping and released. On 22 May 1996 she was recaptured, 530 m from the site of first capture, in a spot where sandy dunes face the sea. Evidently she was in the process of laying eggs, and in fact egg-laying occurred on 30 May 1996 at 0740 h. Three eggs were deposited in a rodent shelter in the sandy soil. This clutch size is consistent with other data for this species (Capula and Luiselli. 1995. Herpetol. Rev. 26:38–39; Luiselli 1995. Rev. Ecol. [Terre et Vie] 50:365–376). The latest contact with this snake occured on 24 October 1996, when she was seen basking on dry leaves, 37 m from the first capture spot and 480 m from the oviposition site.

Because young snakes were frequently seen in the sandy dunes facing the sea, we suggest that female snakes in general tend to use the sandy dunes facing the sea for nesting.

We thank U. Agrimi, F. M. Angelici, M. Capula, B. Hansen, and C. Sisto for critically reviewing of an earlier draft of the manuscript.

LAMPROPELTIS CALLIGASTER CALLIGASTER (Prairie Kingsnake). **ALBINISM.** On 4 September 1996 an amelanistic *Lampropeltis c. calligaster* was collected from under a pile of mulch surrounding a recently planted river birch in Independence, Jackson County, Missouri, USA (T49N, R31W, Sec. 5). The snake (male: 552 mm SVL, 100 mm tail length) is a partial albino with xanthophores, pink eyes, and is similar in appearance to the specimen described by Clark et al. (1983. Herpetol. Rev. 14:120) from adjacent Wyandotte County, Kansas. The snake is currently on display at the Lakeside Nature Center, Kansas City, Missouri, and will be deposited in the Bobby Witcher Memorial Collection at Avila College, Kansas City, Missouri, upon its death.

Submitted by **KEVIN D. HOGAN**, Lakeside Nature Center, 5600 East Gregory Boulevard, Kansas City, Missouri 64132, USA, and **DONALD D. SMITH**, Division of Allergy and Rheumatology, University of Kansas Medical Center, 3901 Rainbow Boulevard, Kansas City, Kansas 66160, USA.

LAMPROPELTIS GETULA FLORIDANA (Florida Kingsnake). Combat Ritual. Combat rituals between male snakes have been recorded in rattlesnakes, *Sistrurus miliarius* (Carpenter 1979. Copeia 1979:638–642) and *Crotalus lepidus* (Carpenter and Murphy 1976. Copeia 1976:764-780), and speckled kingsnakes, *Lampropeltis getula holbrooki* (Carpenter and Gillingham 1977. Southwest. Nat. 22:517–524). Zug (1993. Herpetology: An Introductory Biology of Amphibians and Reptiles. Academic Press, Inc., San Diego, California. 527 pp.) noted that combat rituals in snakes may be performed due to territoriality, or to establish dominance in the presence of a sexually receptive female. Here we describe a combat ritual observed in Florida kingsnakes (*Lampropeltis getula floridana*) in southern Florida. On 7 February 1993, at 1415 h and 24°C, two male *L. g. floridana* were observed along a canal bank just north of Clewiston, in Glades County, Florida, USA. It had been raining all morning, was overcast and very windy. The snakes (116 cm and 130 cm SVL) were first noticed after hearing them rustling in dry grass. The snakes were entwined, with their anterior segments off the ground, biting one another, swaying, and pushing against each other, with each one briefly forcing the other beneath it. After ca. 5 min of observation, both snakes were captured. Both had numerous, bloody bite marks along their bodies, and the largest snake had one hemipenis everted. Although no females were observed in the immediate vicinity, five other *L.g. floridana*, including two females, were captured within 50 m and 0.5 h of these two males, indicating great activity at this time. Our observation suggests that *L.g. floridana* may begin breeding as early as February in southern Florida. All snakes were released at their capture site after data collection.

KRYSKO**, 7575 128 Street N, Seminole, Florida 33776, USA, and **BRIAN DIERKING**, 6338 Baldwyn Avenue, New Port Richey, Florida 34653, USA. *Present address: Department of Wildlife Ecology and Conservation, N-Z Hall, University of Florida, Gainesville, Florida 32611, USA.

PSAMMOPHIS SCHOKARI (Schokari Sand Snake). **DIET.** *Psammophis schokari* is the most widespread and often-encountered snake in Egypt's deserts (pers. obs.); however, little is known about its diet. Flowers (1933. Proc. Zool. Soc. London:735–851) states that he found *P. schokari* hunting in vegetation, probably for lizards of the genera *Mesalina* and *Acanthodactylus*. Schleich et al. (1996. Amphibians and Reptiles of North Africa, Koeltz Scientific Publishers, Koenigstein. 630 pp.) reports *P. schokari* preying on *Agama impalearis*. On 25 June 1997 an immature *Chamaeleo chamaeleon* was found in the stomach of a roadkilled *P. schokari* in the Zaranik Protected Area, North Sinai, Egypt. No other prey was found in the stomach. We believe this is the first record of *C. chamaeleon* in the diet of *P. schokari*. Both specimens were too damaged for measurements. The two species are common and widespread in the sands of North Sinai and share similar desert vegetation microhabitats. The frequency of predation of *C. chamaeleon* by *P. schokari* may thus be potentially high in this region.

We thank Mr. Waheed Salama, Manager of the Zaranik Protected Area, for his hospitality and cooperation.

Submitted by **SHERIF BAHA EL DIN**, Nature Protection Sector, Egyptian Environmental Affairs Agency, 3 Abd Alla El Katib Street, Dokki, Cairo, Egypt, and **OMAR ATTUM**, University of Louisville, 8807 Linn Station Road, Louisville, Kentucky 40222, USA.

RHINOBOTHRYUM LENTIGINOSUM (NCN). **DIET**. Little is known about the diet of the neotropical colubrid *Rhinobothryum lentiginosum*. Cunha and Nascimento (1993. Bol. Mus. Par. Emílio Goeldi sér. Zool. 9:1–191) stated that *R. lentiginosum* feeds on lizards, although they did not provide the number of specimens examined or the lizard taxa found. Here we provide nine substantiated food records of *R. lentiginosum* from Brazilian Amazonia.

Twelve specimens of *R. lentiginosum* were examined. Eleven of these are in the Museu Paraense Emílio Goeldi (MPEG). Data from an additional specimen were provided via personal communication from L. J. Vitt and J. P. Caldwell. The remains of nine prey items were found in six of these snakes (Table 1). Our results indicate that *R. lentiginosum* is a lizard specialist. Further, all prey items are primarily arboreal (unpublished data), indicating that *R. lentiginosum* may forage in the vegetation.

Logistical support and permission to examine snakes at MPEG were kindly provided by T. C. S. Avila-Pires, I. F. F. dos Santos, and A. C. M. Lima. The Conselho Nacional de Desenvolvimento Científico e Tecnológico provided a grant to M. Martins. L. J. Vitt and J. P. Caldwell kindly provided unpublished information.

ASCAPHUS TRUEI (Tailed Frog). USA: CALIFORNIA: Shasta Co: Squaw Creek drainage: unnamed tributary of Horse Creek (a tributary of Squaw Creek), 1 km NW Little Bagley Mountain, SE1/4 of NE1/4 Sec. 35, T37N, R2W. 25 September 1993 (16 tadpoles); Pit River drainage: Baker Creek, tributary of Kosk Creek (a tributary of the Pit River), 4 km NW Big Bend, NW1/4 of NW1/4 Sec. 24, T37N, R1W. 30 March 1994 (KU Color Slide 11252,1 tadpole); Pit River drainage, Shotgun and Little Shotgun Creeks, tributaries of Kosk Creek (a tributary of the Pit River), both 5 km NW Big Bend, center of Sec. 13, T37N, R1W. 4 April 1994 (KU Color Slides 11253–254, 2 and 9 tadpoles, respectively). All observations by Lee and Matthew Simons. Ten specimens from the Squaw Creek drainage sample were sent to Redwood Sciences Laboratory for tissue samples (RSL 1456–1465); the balance were released immediately. Representatives from each site of the Pit River drainage samples were photographed and released. Specimens and slides verified by Hartwell Welsh. First records for each drainage (Bury 1968. Herpetologica 24:39–46; Bury et al. 1969. J. Herpetol. 3:157–161). Pit River drainage samples represent easternmost localities for the species in California (Stebbins 1985. Peterson Field Guide to Western Reptiles and Amphibians. Second ed. Houghton Mifflin Co., Boston, Massachusetts 336 pp.; Hartwell Welsh, pers. comm., 17 September 1992). Many sites in the area remain unsampled. Specimens were handled and collected under permits from the California Department of Fish and Game.

BUFO CRISTATUS. MÉXICO: PUEBLA: Municipio de Zacapoaxtla, Apulco, Cascada de La Gloria, 1500 m elev. (19°55'N, 97°38'W). 6 July 1995. Emilio Roberto Muñoz. Benemerita Universidad Autonoma de Puebla (EBUAP 544–545). Verified by Adrian Nieto Montes de Oca. Extends the known distribution of this species ca. 40 air km ENE of Tezuitlán, Puebla (Mendelson 1997. Herpetologica 53:278). Both are subadult males (SVL 42.7 mm and 37.7 mm, respectively); found in leaf litter in primary cloud forest near the Cascada (waterfall) de La Gloria. Another specimen (TNHC 54943) of this rare species, brought to our attention by David C. Cannatella, lacks any more precise locality data other than "Mexico." This specimen is an adult male (SVL 68.8 mm) and verifies the speculation by Mendelson (1997 *op cit.*:283) that this species lacks vocal slits. This is not the specimen collected and photographed by R. Altig in 1970 (see Mendelson, *op cit*: Fig 6; the most recent sighting of this species before discovery of the individuals reported herein); Altig's specimen was sent alive to W. F. Blair at TNHC (R. Altig, per. comm.), but evidently never was preserved and deposited in a museum.

Submitted by **JOSEPH R. MENDELSON III**, Department of Biology, Utah State University, Logan, Utah 84322, USA, and **LUIS CANSECO-MARQUEZ**, Laboratorio de Herpetología, Escuela de Biología, Benemerita Universidad Autónoma de Puebla, C.P. 72570, Puebla, México.

BUFO TERRESTRIS (Southern Toad). USA: ALABAMA: Dale Co: Fort Rucker Military Reservation. 10 March 1974. V. L. Morris. INHS 10141. Verified by P. W. Smith. New county record (Mount 1975, The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.).

Submitted by **JOHN E. PETZING** and **CHRISTOPHER A. PHILLIPS**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

CHIASMOCLEIS CAPIXABA. BRAZIL: BAHIA: Nova Viçosa (17°53'S, 39°22'W). 7 April 1997. Monique Van Sluys. Museu Nacional do Rio de Janeiro 18924–19025 and 19052–274. Verified by Ulisses Caramaschi. More than 300 individuals fell in pitfalls along drift fences after a night rain. Species was recently described (Cruz et al. 1997. Alytes 15[2]:49–71) from Aracruz, state of Espírito Santo, and was known only the from type local-

ity. First record for the state of Bahia; extends range ca. 600 km north from type locality and represents the northernmost record for the species. Frogs of the genus *Chiasmocleis* are rarely found in nature due to their short breeding period (Kasahara and Haddad 1997. J. Herpetol. 31:139–142).

Submitted by **MONIQUE VAN SLUYS**, Setor de Ecologia, DBAV, IB, Universidade do Estado do Rio de Janeiro, 20550-013, Rio de Janeiro, Rio de Janeiro, Brazil.

ELEUTHERODACTYLUS COQUI (Puerto Rican Coqui). DOMINICAN REPUBLIC: DISTRITO NACIONAL: Santo Domingo, Calle Rosa Duarte No. 21, Gazcue, Santo Domingo 2, República Dominicana (UPRRP 5746–47) and Calle Eric Leonard Ekman No. 10 (Camino del Oeste), Arroyo Hondo, Santo Domingo, República Dominicana (UPRRP 5748). 15 January 1996. R. L. Joglar, N. Rios-López and I. Cruz. Verified by Richard Thomas. Museo de Biología, Universidad de Puerto Rico-Recinto de Río Piedras. First record for Dominican Republic. One population at each of two localities (each now confined to a residence and backyard), within the city limits. Two calling males were collected at Calle Rosa Duarte No. 21, Gazcue, Santo Domingo 2, República Dominicana. This population presumably is established, because juveniles and subadults also were observed. The owner of the residence at this locality enjoyed the coquis melodious calls and, during a visit to Puerto Rico, paid local kids to collect live specimens for transport to the Dominican Republic. At the second locality, Calle Eric Leonard Ekman No. 10 (Camino del Oeste), Arroyo Hondo, Santo Domingo, República Dominicana, two males were heard calling, and four additional individuals were observed (one collected) on a dry night. In December 1992, owners of the residence at this locality moved from Bayamín, Puerto Rico, to Santo Domingo, Dominican Republic, and took with them their houseplants, in which Coquis probably were transported. One year after our first visit (12 January 1997), several males were heard calling at both residences. *Eleutherodactylus coqui* have been introduced in Vieques and Culebra, Puerto Rico (Rivero and Joglar 1979. Herpetol. Rev. 10:101), St. Thomas and St. Croix, U.S. Virgin Islands, southern Florida and Louisiana (Schwartz and Henderson 1991. Amphibians and Reptiles of the West Indies: Descriptions, Distributions and Natural History. Univ. Florida Press, Gainesville. 720 pp.) and in 1994 in Maui, Hawaii (R. Campbell, pers. comm.).

Submitted by **RAFAEL L. JOGLAR** and **NEFTALI RIOS-LÓPEZ**, Departamento de Biología, Universidad de Puerto Rico-Recinto de Río Piedras, Apartado 23360, San Juan Puerto Rico 00931-3360.

HYLA CINEREA (Green Treefrog). USA: ALABAMA: DALE CO: Fort Rucker Military Reservation. 4 June 1974. M. A. Morris. INHS 10303. Verified by M. Redmer. New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.).

Submitted by **JOHN E. PETZING** and **CHRISTOPHER A. PHILLIPS**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

HYLA SQUIRELLA (Squirrel Treefrog). USA: ALABAMA: DALE CO: 8 km S Daleville. 3 August 1974. J. C. Morris. INHS 10143. Verified by M. Redmer. New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.).

Submitted by **JOHN E. PETZING** and **CHRISTOPHER A. PHILLIPS**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

HYLA VIGILANS. VENEZUELA: FALCÓN: Municipio Monseñor Iturriza, Sanare (ca. 10°52'N, 68°23'W). No date. Ramón A. Rivero. EBRG 2968. Verified by Jesús Manzanilla. First report from the state of Falcón, and the northwesternmost report of the species (La Marca 1992, Cuad. Geogr. Univ. Los Andes, Mérida 9:1–197).

Submitted by **ABRAHAM MIJARES-URRUTIA**, **ALEXIS ARENDS**, Centro de Investigaciones en Ecología y Zonas Áridas (CIEZA), Universidad Francisco de Miranda, Apartado 7506, Coro 4101-A, Venezuela (e-mail: amijares@funflc.org.ve/aarends@reacciun.ve) and **RAMÓN A. RIVERO**, Estación Biológica El Limón, Servicio Autónomo PROFAUNA, Ministerio del Ambiente y de los Recursos Naturales Renovables, Apartado 184, Maracay, Venezuela.

OSTEOPILUS SEPTENTRIONALIS (Cuban Treefrog, Rana Platanera). PUERTO RICO: COAMO: (18°05'00"N, 66°21'30"W) at the Criminal Investigation Bureau building. 13 July 1997. Sr. Norat, Sergio Serrano, and Carlos Rosa. Verified by Richard Thomas. Museo de Biología, Universidad de Puerto Rico-Recinto de Río Piedras. (UPRRP 5749). One adult female was collected. New record; extends range ca. 50 km southwest and is first record for the southern part of island. Species was introduced in Puerto Rico in the 1950s (Thomas and Joglar 1996. *In* J. Figueroa, ed., The Scientific Survey of Puerto Rico and The Virgin Islands, pp. 181–196. Ann. New York Acad. Sci. Vol. 776). In 1978, the frog was reported as inhabiting the Aguadilla, Isabela, Quebradillas area in northwestern Puerto Rico (Rivero 1978. Los Anfibios y Reptiles de Puerto Rico. Editorial Universitaria U. P. R. San Juan. 152 pp.). By 1995, it had expanded its range ca. 100 km east into northeastern Puerto Rico (Joglar and Rios López 1995. Herpetol. Rev. 26:105–106).

Submitted by **RAFAEL L. JOGLAR**, **NEFTALÍ RIOS-LÓPEZ**, and **MARÍA CARDONA**, Departamento de Biología, Universidad de Puerto Rico-Recinto de Río Piedras, Apartado 23360, San Juan Puerto Rico 00931-3360.

POLYPEDATES LEUCOMYSTAX (Java Whipping Frog). JAPAN: OKINAWA PREFECTURE: Miyakojima Island, Miyako Island Group, in sugarcane field in the town of Gusukube, ca. 2.7 km SSE Miyako Branch of Okinawa Prefectural Agricultural Experiment Station, 22°44'70"N, 125°20'57"E. 12 February 1998. Setsuko Iwanaga. Zoological Collection of Kyoto University (KUZ 47305). Verified by Hidetoshi Ota. Adult male perched on sugarcane stalk. First record for island group. Species was artificially introduced into Japan from southeastern Asia after World War II. In Japan, its range has been confined to Okinawajima and a few adjacent islets of the Okinawa Island Group (Ota 1995. Island Stud. Okinawa 13:63–78).

Submitted by **SETSUKO IWANAGA**, Laboratory of Sugarcane Insect, Okinawa Prefectural Agricultural Experiment Station, 4-222 Sakiyama, Naha, Okinawa 903-0814, Japan.

PSEUDACRIS CRUCIFER (Spring Peeper). USA: ILLINOIS: JASPER CO: 6.25 km SSE Newton and just SW (5 m) jct of Co. Rd. 1000E and Co. Rd. 500N (NW 1/4, NW 1/4 Sec. 34, T6N, R9E; UTM Zone 16: N4308455m, E396970m). 6 August 1997. D. J.

Olson. Illinois Natural History Survey (INHS 13869). Verified by C. A. Phillips. New county record filling gap in expected distribution (Smith 1961. The Amphibians and Reptiles of Illinois. Illinois Nat. His. Surv. Bull. 298 pp.).

Submitted by **DANIEL J. OLSON**, Department of Biological Sciences, Eastern Illinois University, Charleston, Illinois 61920, USA.

PSEUDACRIS CRUCIFER (Spring Peeper). USA: LOUISIANA: BEAUREGARD PARISH: Camp Edgewood area, from jct U.S. Rt. 171 and U.S. Rt. 190 at Ragley, 6.5 mi S on U.S. Rt. 171, 6 mi W on Camp Edgewood Road. 6 February 1986. Doyle, Esters, and Thomas. Seale Museum of Louisiana, McNeese State University (SML 8483). 10 March 1987. Goodwin and Lovinggood. SML 8544. Both specimens verified by Jeff Boundy. First parish record as mapped by Dundee and Rossman (1989, The Amphibians and Reptiles of Louisiana, Louisiana St. Univ. Press, Baton Rouge. 300 pp.).

Submitted by **AVERY A. WILLIAMS**, Division of Sciences, Louisiana State University at Eunice, Eunice, Louisiana 70535, USA.

PSEUDACRIS FERIARUM (Upland Chorus Frog). USA: LOUISIANA: JEFFERSON DAVIS PARISH: Topsy area, from U.S. Rt. 190 at Bel, 8 mi S on Topsy-Bel Road. 12 February 1998. Avery A. Williams. Seale Museum of Louisiana, McNeese State University (SML 9314–15). Both specimens verified by Jeff Boundy. First parish record (Dundee and Rossman 1989. RANA CLAMITANS (Green Frog). USA: ILLINOIS: PIKE CO: 3.5 km SSE Kinderhook, Grubb Hollow along Co. Rd. 1950N, just E Ill. Rt. 96 (SE 1/4 Sec. 31, T14S, R6W; UTM Zone 15: N4393040m, E660150m). 21 October 1997. J. E. Petzing and C. A. Phillips. INHS 13402. Verified by M. J. Dreslik. New county record.

Submitted by **JOHN E. PETZING** and **CHRISTOPHER A. PHILLIPS**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

RANA CLAMITANS (Green Frog). USA: MISSOURI: PERRY CO: 19 km E Perryville (37°42'07"N, 89°37'12"W) by a spring. 15 October 1994. B. Churchwell, J. Krejca, and S. Taylor. SIUC H-4776. Verified by R. A. Brandon. County record; fills gap between Bollinger, Cape Girardeau, St. Francois, and Ste. Genevieve counties (Johnson 1987. The Amphibians and Reptiles of Missouri. Publ. Missouri Dept. Conserv., Jefferson City. 368 pp; Powell et al. 1993, Missouri Herpetol. Assoc. Newsl. 6:7–26).

Submitted by **STEVEN J. TAYLOR**, Center for Biodiversity, Illinois Natural History Survey, 607 East Peabody Drive, Champaign, Illinois 61820, USA, **JEAN K. KREJCA**, Department of Zoology, University of Texas, Austin, Texas 78712-1064, USA, and **BETH CHURCHWELL**, The Nature Conservancy, 2800 South Brentwood Boulevard, St. Louis, Missouri 63144, USA.

RANA CLAMITANS CLAMITANS (Bronze Frog). USA: ILLINOIS: KANE CO: West branch Big Rock Creek and Rt. 30, Sec. 21, T38N, R6E. 27 August 1970. D.W. Greenfield and Gary Decker. NIU-HDW (1614). Verified by P. L. Meserve. New county record.

Submitted by **HARLAN D. WALLEY**, Northern Illinois University, Dekalb, Illinois 60115, USA.

SCAPHIOPUS COUCHII (Couch's Spadefoot) USA: COLORADO: OTERO CO: AOR, Co. Rd. 2, 2.4 mi S jct. Co. Rd. KK. 24 August 1997. University of Northern Colorado Museum of Natural History (UNC-MNH Photograph 27). Verified by Hobart M. Smith and David Chiszar. Specimen represents a range extension of ca. 40 mi NW of known Colorado populations (Livo et al. 1996. Herpetological Micro-biogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **CHAD MONTGOMERY**, **JAMES SIFERT**, **BEN HILL**, **THERESA CHILDERS**, **JERRY D. MANZER**, **ENOCH BERGMAN** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

SPEA MULTIPLICATA (New Mexico Spadefoot). USA: COLORADO: PUEBLO CO: Line 27, Station 2. 24 July 1967. Collector unknown. UCM 59555-59556; Boone, Grid A, Line 1, Station 25-28. 30 June 1967. Collector unknown. UCM 59557. Both verified by Hobart M. Smith. New county record (Hammerson 1982. Amphibians and Reptiles in Colorado. Publ. Colorado Division of Wildlife).

Submitted by **KYLE G. ASHTON**, Department of EPO Biology, University of Colorado, Boulder, Colorado 80309, USA.

SYRRHOPHUS CYSTIGNATHOIDES (Rio Grande Chirping Frog) USA: TEXAS: FAYETTE CO: fairgrounds (29°55'31"N, 96°52'54"W) below sandstone cliffs on hill along the Colorado River flood plain. Juvenile female collected 11 February 1998; adult male collected 8 March 1998. Andre de la Reza, Collin Balcombe, and Todd Schlenke. Verified by David Cannatella. TNHC 56738–39 (DCC 3566–67). This resident of the Rio Grande Valley was probably introduced into the San Antonio, Houston, Fort Worth, and Tyler areas via the potted plant trade (Brach 1992.

Texas J. Sci. 44:490; Dixon 1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station, 434 pp; McGown et al. 1994. Herpetol. Rev. 25:32). This also seems the most likely reason for its introduction into Fayette County.

Submitted by **ANDRE G. DE LA REZA**, **COLLIN BALCOMBE**, and **TODD SCHLENKE**, Department of Zoology, University of Texas, Austin, Texas 78712, USA.

TESTUDINES

CHELYDRA SERPENTINA SERPENTINA (Common Snapping Turtle) USA: COLORADO: Kiowa Co: Adobe Creek beneath Co. Rd. E, 1.4 mi E jct Rt. 96. 11 May 1997. University of Northern Colorado Museum of Natural History (UNC-MNH Photograph 22). Verified by Hobart M. Smith and David Chiszar. County record (Livo et al. 1996. Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **JUSTIN HOBERT**, **CHAD MONTGOMERY**, **THERESA CHILDERS**, **JERRY D. MANZER**, **ENOCH BERGMAN**, **JAMES SIFERT**, **BEN HILL,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

GRAPTEMYS OUACHITENSIS (Ouachita Map Turtle). USA: KANSAS: Russell Co: Wilson Reservoir, Sec. 32, T12S, R12W. 25 October 1996. Tommie Berger. KU 224654. Verified by Lynnette Sievert. New county record; represents the most northwestern record for Kansas (Collins 1993. Amphibians and Reptiles in Kansas. Third Ed. Univ. Press Kansas, Lawrence. xx + 397 pp.).

Submitted by **GREGORY SIEVERT**, Division of Biological Sciences, Emporia State University, Emporia, Kansas 66047, USA, and **JOSEPH T. COLLINS**, The Center for North American Amphibians and Reptiles, 1502 Medinah Circle, Lawrence, Kansas 66047, USA.

KACHUGA SMITHII SMITHII (Brown Roofed Turtle). NEPAL: border of Saptari/Sunsari Districts (Koshi River at Koshi Barrage, 26°32'N, 86°55'E). 20 June 1996. David Edds. Chitwan National Park (Nepal) turtle collection (DE-NT 9). Verified by T. M. Maskey. First record of this subspecies from Nepal. Moll (1987. J. Bombay Nat. Hist. Soc. 84:7–25) described a new subspecies, *K. s. pallidipes,* including a paratype from the Karnali River in western Nepal (three specimens of which were captured in the Karnali by the author in 1996: DE-NT 10–12); characteristics of this single specimen from eastern Nepal clearly correspond to those of the nominate race, including profuse pigmentation of the head, limbs, penis, and plastron. Sympatric with *K. tentoria flaviventer.* Mitchell and Rhodin (1996. Chelonian Conserv. Biol. 2:66–72) noted decorated shells of *K. smithii* for sale as ceremonial artifact masks in Kathmandu.

Submitted by **DAVID EDDS**, Division of Biological Sciences, Emporia State University, Emporia, Kansas 66801, USA.

KACHUGA TECTA (Indian Roofed Turtle). NEPAL: Nawalparasi District (Narayani River at Tribenighat 27°27'N, 83°55'E). 10 April 1996. David Edds. Chitwan National Park (Nepal) turtle collection (DE-NT 6). Verified by T. M. Maskey. Second record from Nepal, following Hall (1980. J. Bombay Nat. Hist. Soc. 77:521–522), and extending Nepal distribution ca. 215 km west. Das (1991. Colour Guide to the Turtles and Tortoises of the Indian Subcontinent. R & A Publishing Ltd., Avon, England. 133 pp.) and Mitchell and Rhodin (1996. Chelonian Conserv. Biol. 2:66–72) noted Hall's record from eastern Janakpur (Dhanusa District); Moll (1987. J. Bombay Nat. Hist. Soc. 84:7–25) and Iverson (1992. A Revised Checklist with Distribution Maps of the Turtles of the World. Richmond, Indiana. 363 pp.) suspected the species existed in Nepal. In vegetation-choked waters; sympatric with *K. tentoria flaviventer.*

Submitted by **DAVID EDDS**, Division of Biological Sciences, Emporia State University, Emporia, Kansas 66801, USA.

KACHUGA TENTORIA FLAVIVENTER (Yellowbelly Indian Tent Turtle). NEPAL: Nawalparasi District (Narayani River at Tribenighat 27°27'N, 83°55'E) and border of Saptari/Sunsari Districts (Koshi River at Koshi Barrage 26°32'N, 86°55'E). 10 April 1996 and 20 June 1996. David Edds. Chitwan National Park (Nepal) turtle collection (DE-NT 7–8). Verified by T. M. Maskey and K. B. Shah. First records of *K. tentoria* from Nepal. In vegetation-choked waters; sympatric with *K. tecta* in Narayani, and with *K. s. smithii* in Koshi. Moll (1987. J. Bombay Nat. Hist. Soc. 84:7–25), Das (1991. Colour Guide to the Turtles and Tortoises of the Indian Subcontinent. R & A Publishing Ltd., Avon, England. 133 pp.) and Iverson (1992. A Revised Checklist with Distribution Maps of the Turtles of the World. Richmond, Indiana. 363 pp.) noted *K. t. flaviventer* from tributaries of the Ganges River in northern India.

Submitted by **DAVID EDDS**, Division of Biological Sciences, Emporia State University, Emporia, Kansas 66801, USA.

TERRAPENE ORNATA (Ornate Box Turtle). USA: TEXAS: Rockwall co: Rockwall. 12 May 1997. Photographed by Dixon Glaze. The specimen was found on private property and was only allowed to be photographed. Verified by C. J. Franklin. University of Texas at Arlington (UTA Color Slide 23641). New county record (Dixon 1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.).

Submitted by **CARL J. FRANKLIN**, Dallas Zoo, Department of Herpetology, 650 South R. L. Thorton Freeway, Dallas, Texas 75203, USA, and **DIXON GLAZE**, Rockwall, Texas, USA.

TRACHEMYS SCRIPTA (Slider). USA: ALABAMA: Wilcox Co: 2.4 km W Camden and 0.8 km E jct Alabama Rts. 221/164, backwater of Alabama River at Alabama Rt. 10 (31°59.573'N, 87°19.613'W). 12 March 1996. J. M. Serb and T. J. Near. INHS 12254. Verified by C. A. Phillips. New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.).

Submitted by **JEANNE M. SERB**, **THOMAS J. NEAR,** and **JOHN E. PETZING**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

LACERTILIA

AMEIVA BIFRONTATA. VENEZUELA: ESTADO ARAGUA: Municipio Mario Bricego Iragori, trail between Bahía de Cata and Playa Catica, Parque Nacional Henri Pittier, 10°30'N, 67°44'W, 90 m elev. February 1993. R. Cornieles. Museo del Instituto de Zoología Agrícola, Facultad de Agronomía, Universidad Central de Venezuela, Maracay (MIZA 15-354, 15-355) Verified by R. Rivero. Specimens constitute the first record for the state of Aragua and the Parque Nacional Henri Pittier

(Manzanilla 1996. Acta Cient. Venezuela 47[3]:1–12) and fill the distributional gaps between the states of Miranda and Sucre in the east, and the state of Falcon in the west (Lesn and Ruiz 1971. Caribbean J. Sci. 11[3-4]:195–201; Cordero 1987. Acta Cient. Venezuela 38:234–258; Bisbal 1990. Acta Cient. Venezuela 41[3]:177–185).

Submitted by **JESUS MANZANILLA**, **RICARDO CORNIELES,** and **ALBERTO FERNANDEZ-BADILLO**, Museo del Instituto de Zoología Agrícola, Facultad de Agronomía, Universidad Central de Venezuela, Maracay, Venezuela.

ANOLIS CAROLINENSIS (Green Anole). USA: GEORGIA: CANDLER CO: 1.6 km W Metter. 23 June 1977. L. M. Page, M. A. Morris, and R. L. Mayden. INHS 10407. Verified by P. W. Smith. New county record (Williamson and Moulis 1994. Distribution of Amphibians and Reptiles in Georgia. 2 Vols. Savannah Sci. Mus. Spec. Publ. 3:1–712).

Submitted by **JOHN E. PETZING** and **CHRISTOPHER A. PHILLIPS**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

GALLOTIA GALLOTI EISENTRAUTI. SPAIN: CANARY ISLAND: EL HIERRO ISLAND: El Matorral, Frontera (UTM 3075789/203253). 16 May 1997. Miguel A. Rodríguez-Domínguez. Recovering Center for The Hierro's Giant Lizard, Canary Government (CR 971116). Verified by M. Molina-Borja. First record for El Hierro island. Adult male collected in a tropical pineapple property with several fruit-bearing trees. Two other live individuals were observed, but not captured. The subspecies was known only from Tenerife Island (Bischoff 1982. Bonn. zool. Beitr. 33:363–382). The method of introduction of this species is not known. However, the area where lizards were found is very close to an Agriculture Product Cooperative, and merchandise trucks arrive regularly from Tenerife. We believe that they have been recently and accidentally introduced by humans in this manner to El Hierro Island.

Submitted by **MIGUEL A. RODRÍGUEZ-DOMÍNGUEZ** and **MIGUEL RUÍZ-CABALLERO**, Recovering Center for The Hierro's Giant Lizard, Canary Government, Frontera 38911, El Hierro, Canary Islands, Spain.

GERRHONOTUS LIOCEPHALUS (Texas Alligator lizard). MÉXICO: AGUASCALIENTES: Los Alisos, Sierra del Laurel, municipality of Calvillo (21°58'N, 102°45'W) in oak forest. 22 October 1983. Gilfredo de la Riva. Departamento de Biología, Universidad Autónoma de Aguascalientes. Verified by Mario Mancilla. Nearest records of *G. l. liocephalus* are from 3 km N Pueblo Nuevo, Municipio El Salto, 9 km SE Llano Grande, Municipio Durango, Durango, and 19.2 km NE Santa Lucía, 1990 m, in Sinaloa (Good 1994. Herpetol. Monogr. 8:180–202).

Submitted by **AURELIO RAMIREZ-BAUTISTA**, Instituto de Biología, Departamento de Zoología, Universidad Nacional Autónoma de México, Apartado Postal 70-153, México, Distrito Federal 04510, México, **JOEL VAZQUEZ-DIAZ** and **GUSTAVO QUINTERO-DIAZ**, Universidad Autónoma de Aguascalientes, Centro Básico, Departamento de Biología, Avenida Universidad 940, C.P. 20100, Aguascalientes, Aguascalientes, México.

HOLBROOKIA MACULATA BUNKERI (Bunker's Earless Lizard). NEW MEXICO: DOÑA ANA CO: 32–55 km E El Paso. 27 June and 1 August 1970. W. S. Parker. LACM 113389–90. LUNA CO: 8 km E and 2 km S Hermanas. 22 June 1992. J. N. Stuart. MSB 54265. All verified by Ralph W. Axtell. First record for New Mexico (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. 431 pp.) and United States. Supported by range extensions northward from previous records on the dunes near Samalayuca, Chihuahua, México, at El Tule [Escuela Nacional de Estudios Profesionales Iztacala (= ENEPI) field nos. 36320–3, 36326]; Los Chontes (ENEPI 36327, 36339–40); Las Coates (ENEPI 36356); and eastward, at Puerto Ancho (ENEPI 36367–70), Chihuahua, collected in June 1997 by four of the authors and Adam Chiszar. The New Mexico specimens include two males with T/SV ratios of 1.25 and 1.37, and one female with a ratio of 0.91, all within the known range of *H. m. bunkeri* (males 1.0–1.37, females 0.91–1.14). The available UCM material of the other subspecies in New Mexico have ratios in *H. m. approximans* (auctorum) of 0.70–1.02 in 20 males, and 0.62–0.90 in 25 females from various localities in western New Mexico, southwestern Colorado and central eastern Arizona, and in *H. m. ruthveni* of 0.87–0.97 in 14 males, 0.72–0.90 in 10 females.

Submitted by **HOBART M. SMITH**, **DAVID CHISZAR**, **CLINT HENKE,** and **FRANK VAN BREUKELEN**, University of Colorado Museum, Boulder, Colorado 80309-0218, USA; and **JULIO A. LEMOS-ESPINAL**, Laboratorio de Ecologia, Unidad de Biologia, Tecnologia y Prototipos, Escuela Nacional de Estudios Profesionales Iztacala, Universidad Nacional Autónoma de México, Apartado Postal 314, Tlalnepantla, Estado de México, México.

LEPIDODACTYLUS LUGUBRIS (Mourning Gecko). ECUADOR: GALAPAGOS ISLANDS: Isla Santa Cruz in Puerto Ayora. 14 June 1997. Showichi Sengoku. Japan Wildlife Research Center Photo Collection Color Slide No. 97060125. Verified by Hidetoshi Ota. Several individuals around garden lanterns of the Hotel Galapagos at night (1800-2400 h). A number of individuals of this gecko, together with few *Phyllodactylus galapagensis* (Galapagos Leaf-toed Gecko), observed not only around garden lanterns, but also on outside walls of the hotel during the second visit from 25–29 June 1997. Islands record; lending support to Hoogmoed (1989. Not. Galapagos [47]:12–16), who listed this species as occurring in the Galapagos Islands, but without providing evidence.

Submitted by **SHOWICHI SENGOKU**, Japan Wildlife Research Center, Yushima 2-29-3, Bunkyo-ku, Tokyo 113, Japan.

PHRYNOSOMA CORNUTUM (Texas Horned Lizard) USA: COLORADO: PUEBLO CO: DOR, Co. Rd. 10, 0.2 mi NE Co. Rd. 707 (Pipeline Road). 24 August 1997. University of Northern Colorado Museum of Natural History (UNC-MNH 797). Verified by Hobart M. Smith and David Chiszar. County record (Livo et al. 1996. Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **CHAD MONTGOMERY**, **THERESA CHILDERS**, **JERRY D. MANZER**, **ENOCH BERGMAN**, **JAMES SIFERT**, **BEN HILL,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

PHRYNOSOMA DITMARSI (Rock Horned Lizard). MÉXICO: SONORA: thornscrub hillside at El Chorro, 8 km (by road) NE

of Nácori Chico (Municipio Nácori Chico), ca. 1000 m elev. 4 September 1984. C. H. Lowe and B. E. Martin. UAZ 45884 (male, SVL 64 mm) with 11 color slides. Verified by Peter A. Holm and Philip C. Rosen. This is only the fourth known locality record for an endemic Sonoran species whose existence was lost to science for 73 years (Lowe et al. 1971. J. Arizona Acad. Sci. 6[4]:277; Roth 1997. Sonoran Herpetologist 10:2–6; Sherbrooke 1997. Sonoran Herpetologist 10[1]:6–8). The new locality is 140 km NNE of another report, also in the drainage of the Río Yaqui (Perrill 1983. Herpetol. Rev. 14:123], whereas the two earlier locality reports (Lowe et al. 1971, *op. cit.*; Lowe and Howard 1975. Southwest. Nat. 20:264–270) were in the more westerly Río Sonora drainage (Baviacora is 115 km directly west) in Madrean evergreen woodlands. Both Río Yaqui localities establish the use of thornforest/scrub habitat by this species, and suggest that additional populations, perhaps isolated in varied habitats, may be located. Currently the Rock Horned Lizard is listed as threatened by the Mexican government, but remains unstudied in the field.

Submitted by **WADE C. SHERBROOKE**, Southwestern Research Station, American Museum of Natural History, P.O. Box 16553, Portal, Arizona 85632, USA, and **BRENT E. MARTIN** and **CHARLES H. LOWE**, Department of Ecology and Evolutionary Biology, University of Arizona, Tucson, Arizona 85721, USA.

PHRYNOSOMA DOUGLASII (Short-horned Lizard) USA: COLORADO: Kiowa Co: DOR, Co. Rd. E, 0.2 mi E jct. Rt. 96 (38°19.434'N, 103°20.611'W). 15 August 1997. University of Northern Colorado Museum of Natural History (UNC-MNH 767). Verified by Hobart M. Smith and David Chiszar. County record (Livo et al. 1996. Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **ENOCH BERGMAN**, **BEN HILL**, **CHAD MONTGOMERY**, **THERESA CHILDERS**, **JERRY D. MANZER**, **JAMES SIFERT**, and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

SCELOPORUS UNDULATUS (Fence Lizard). USA: ALABAMA: Escambia Co: W of Brewton, Burnt Corn Creek at Ala. Rt. 41 (31°07.776'N, 87°05.253'W). 11 March 1996. P. A. Ceas, J. M. Serb, J. C. Porterfield, and T. J. Near. INHS 12250. Verified by C. A. Phillips. New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.).

Submitted by **JEANNE M. SERB**, **JOHN E. PETZING**, and **THOMAS J. NEAR**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

TROPIDURUS STROBILURUS (Lava Lizard). BRAZIL: ESPIRITO SANTO: Município de Presidente Kennedy, Praia das Neves (21°16'S, 40°48'W). 30 January 1996. G. J. Zerbini and A. F. B. Araujo. Universidade de Brasília (UnB 2175). Verified by G. R. Colli. First record for the state of South Espírito Santo; known along the Atlantic Forest from the state of Pernambuco to Santa Cruz in the state of Espírito Santo (Jackson 1978. Arq. Zool. São Paulo 30:1–79). Praia das Neves is the most meridional record for this species and about 250 km S of Santa Cruz. The specimens were found in an isolated 70 ha fragment of "Mata de Restinga" vegetation, about 1 km from the beach.

Submitted by **GLAUCIA JORDÃO ZERBINI**, **ELISABETH M. M. DA COSTA**, **ALEXANDRE F. B. ARAUJO**, and **REUBER A. BRANDÃO**, Departamento de Zoologia-ZOO/IB, Universidade de Brasília, 70 910-900, Brasília, Distrito Federal, Brazil.

SERPENTES

AGKISTRODON CONTORTRIX (Copperhead). USA: ALABAMA: Dale Co: Fort Rucker Military Reservation. 14 April 1974. M. A. Morris and S. S. Morris. INHS 10165. Verified by P. W. Smith. New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.).

Submitted by **JOHN E. PETZING** and **CHRISTOPHER A. PHILLIPS**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

CROTALUS TIGRIS (Tiger Rattlesnake). USA: ARIZONA: Cochise Co: Peloncillo Mountains, Sec. 32, T22S, R32E. 30 July 1995. Andrew T. Holycross. Museum of Vertebrate Zoology (MVZ photograph). Verified by Harry W. Greene. A female *C. tigris* was captured crossing Geronimo Trail 3.2 km E of the Cottonwood Cemetery driveway among foothills dominated by *Fouqueria* and *Opuntia* spp. Specimen photographed and blood taken from the caudal vein. Extends range 17 km N of Guadalupe Canyon and the only other specimen reported from this range (Painter and Milensky 1993. Herpetol. Rev. 24:155–156) and E of the Santa Rita Mountains in southeastern Arizona.

Submitted by **ANDREW T. HOLYCROSS**, Zoology Department, Arizona State University, Tempe, Arizona 85287-1501, USA.

DIADOPHIS PUNCTATUS (Ringneck Snake). USA: ALABAMA: Dale Co: Fort Rucker Military Reservation. 13 February 1971. M. A. Morris. INHS 10158. Verified by P. W. Smith. New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.).

Submitted by **JOHN E. PETZING** and **CHRISTOPHER A. PHILLIPS**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

DINODON RUFOZONATUM (Red Banded Snake). RUSSIA: PRIMORSKY REGION: Nadezhdinsky District: ca. 15 km W Venevitinovo Village near Bolshevistsky Creek, 2 km upstream from its jct with Malaya Elduga River, 43°28'N, 141°25'E. 8 July 1995. A. Kotlobay and D. Maslov. Zoological Museum of M. V. Lomonosov University, Moscow, Russia (Cat. No. R-10294). Verified by V. F. Orlova. Confirms previous unverified records of species for Primorsky region (Zhao and Adler 1993. Herpetology of China. Publ. Soc. Study Amphib. Rept., Oxford, Ohio. 522 pp.). The female specimen was captured in rubbish near the creek. In 1987, another adult was captured and one more was sighted by D. Maslov in the M. Elduga River Valley on a forest road, flooded after a strong rain. In 1988, an adult was captured near a hunter's cabin at Bolshevistsky Creek by P. Tupeleev. In 1989, a dead adult was found by V. Solkin near the river.

Submitted by **DMITRI A. MASLOV**, Department of Biology, University of California, Riverside, California 92521, USA, and

ANATOLY A. KOTLOBAY, Department of Biochemistry, School of Biology, Moscow State University, 119899 Moscow, Russia.

ELAPHE EMORYI (Great Plains Rat Snake). USA: NEW MEXICO: Otero Co: White Sands Missle Range, Range Road 9 at Malpais Springs, ca. 27.4 km W and 23.3 km N Tularosa. 31 July 1997. Doug Burkett and Larry Kamees. University of New Mexico Museum of Southwestern Biology (MSB 60999). Verified by D. S. Sias. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **DOUG BURKETT** and **LARRY KAMEES**, P.O. Box 399, White Sands Missle Range, New Mexico 88002, USA, and **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA.

ELAPHE GUTTATA (Corn Snake). USA: ALABAMA: Dale Co: Fort Rucker Military Reservation. 20 July 1974. M. A. Morris and R. C. Morris. INHS 10166. Verified by P. W. Smith. New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Univ. Agric. Exp. Sta., Auburn, Alabama. 347 pp.).

Submitted by **JOHN E. PETZING** and **CHRISTOPHER A. PHILLIPS**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

ELAPHE GUTTATA EMORYI (Great Plains Rat Snake). USA: COLORADO: Prowers Co: AOR Co. Rd. 13, 0.1 mi N Baca Co. line. 3 June 1997. University of Northern Colorado Museum of Natural History (UNC-MNH Photograph 23). Verified by Hobart M. Smith and David Chiszar. Adult specimen; represents a southeast range extension of ca. 35 miles and northwestern extension of 40 miles. A hatchling second specimen (Baca County, on canyon wall east side of Co. Rd. 30 at Two Buttes Dam on 23 September 1997) was found within 1 mile of the first specimen (Livo et al. 1996. Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **CHAD MONTGOMERY**, **LEEANN COMPTON**, **THERESA CHILDERS**, **ENOCH BERGMAN**, **JERRY D. MANZER**, **JAMES SIFERT**, **BEN HILL**, and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

ELAPHE GUTTATA MEAHLLMORUM (Southern Plains Rat Snake) MÉXICO: HIDALGO: Huejutla: Huejutla, Hotel Rivera (21°08'36"N, 98°25'12"W), ca. 150 m elev. 1 November 1995. Ricardo Reyes Avila. Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autonoma de México (MSFC 8436). Verified by Andrián Nieto Montes de Oca. First record for Hidalgo; extends range ca. 152.8 km SE and 126.4 km E of closest known localities at 30 mi N Valles, San Luis Potosí and Old Mill at Hacienda San Nicolás Conca (Sharpton's Finca), 10.4 mi S Arroyo Seco, San Luis Potosí, as reported by Smith et al. (1994. Texas J. Sci. 46:259–292). The presence of this species in Huejutla is probably due to human introduction.

Submitted by **FERNANDO MENDOZA QUIJANO**, Instituto Tecnológico Agropecuario No. 6, Km 5.5 Carr. Huejutla-Chalahuiyapa, Apartado Postal 94, Huejutla de Reyes, C.P. 43000, Hidalgo, México, (e-mail: mendoza@mail.ibiología.unam.mx), **RICARDO REYES AVILA** and **LAURA CONTRERAS NARVAEZ**, Museo de Zoología, Facultad de Ciencias, Universidad Nacional Autonoma de México, Apartado Postal 70-399, México Distrito Federal 04510, México.

ELAPHE OBSOLETA LINDHEIMERII (Texas Rat Snake). USA: COLORADO: Kiowa Co: DOR, Rt. 287, 1.6 mi S jct. Co. Rd. N (38°25.046'N, 102°43.763'W). University of Northern Colorado Museum of Natural History (UNC-MNH 848). Verified by Hobart M. Smith and David Chiszar. First state record (Livo et al. 1996. Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.); specimen represents a range extension of ca. 200 miles from Kansas populations of *Elaphe obsoleta* and ca. 180 miles from Oklahoma populations of *E. o. lindheimerii* (Conant and Collins 1991. Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third edition. Houghton Mifflin Co., Boston, Massachusetts. xviii + 450 pp.).

Submitted by **CHAD MONTGOMERY**, **THERESA CHILDERS**, **JERRY D. MANZER**, **ENOCH BERGMAN**, **JAMES SIFERT**, **BEN HILL**, and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

FARANCIA ABACURA (Mud Snake). USA: GEORGIA: Calhoun Co: 2.4 km S Leary. 13 May 1972. L. R. Davis. INHS 10003. Verified by P. W. Smith. New county record (Williamson and Moulis 1994. Distribution of Amphibians and Reptiles in Georgia. 2 Vols. Savannah Sci. Mus. Spec. Publ. 3:1–712).

Submitted by **JOHN E. PETZING** and **CHRISTOPHER A. PHILLIPS**, Illinois Natural History Survey, Center for Biodiversity, 172 Natural Resources Building, 607 East Peabody Drive, Champaign, Illinois 61820, USA.

GOMESOPHIS BRASILIENSIS (Brazilian Burrowing Snake). BRAZIL: DISTRITO FEDERAL: Estação Ecológica de Águas Emendadas: Lagoa Bonita (15°35'S, 47°41'W). 26 May 1992. Reuber A. Brandão and Victor S-J Perdigão. Universidade de Brasília (UNB 2970). Verified by T. de Lema. First record for central Brazil. Species was known from states of Rio Grande do Sul, Santa Catarina, Paraná, São Paulo and Minas Gerais (Peters and Orejas-Miranda 1970. Bull. U.S. Natl. Mus. 297:1–347). In Estação Ecológica de Águas Emendadas, streams of three major Brazilian hydrographic basins (Amazon, São Francisco, and Platina) come together. The Rio Mestre D´Armas belongs to the Platina Basin and its margins are covered with gallery forest, which may represent a pathway for faunal dispersal (Vanzolini 1994. Ann. Acad. Bras. Ci. 66 [supl.1]:173–176) between the Cerrado (mainly known as "Chapadas do Brasil Central") and neighboring vegetational systems, and contributes to lower the level of endemism found in the Cerrado (Cerqueira 1982. *In* Mares and Genoways (eds.), Mammalian Biology in South America, pp. 53–75. Univ. Pittsburgh Press, Pittsburgh, Pennsylvania). This new distributional record may corroborate their hypothesis.

Submitted by **ANA LÚCIA DA COSTA PRUDENTE**, Curso de Pós-Graduação em Zoologia, Universidade Federal do Paraná, CP 19020, CEP 81.531-990, Curitiba, Paraná, Brazil, and **REUBER A. BRANDÃO**, Laboratório de Fisiologia Animal - CFS/IB, Universidade de Brasília, CEP 70.910-900, Brasília, Distrito Federal, Brazil.

HETERODON NASICUS (Western Hognose Snake). MÉXICO: AGUASCALIENTES: municipality of Aguascalientes (21°57'N, 102°17'W) in grassland and dry forest. 1 November 1991. Gilfredo de la Riva. Universidad Autónoma de Aguascalientes, Centro Básico, Departamento de Biología (UAA-VR 00209). Verified by Carlos Balderas. First record for state of Aguscalientes; extends range ca. 160 km SE of Zacatecas, 210 km SW of San Luis Postosí (Platt 1969. Univ. Kansas Publ. Mus. Nat. Hist. 18:253–420) and 125 km NW of Jalisco (Pérez-Ramos 1987. Herpetol. Rev. 18:56).

Submitted by **JOEL VAZQUEZ-DIAZ** and **GUSTAVO QUINTERO-DIAZ**, Universidad Autónoma de Aguascalientes, Centro Básico, Departamento de Biología, Avenida Universidad 940, C.P. 20100, Aguascalientes, Aguascalientes, México, and **AURELIO RAMIREZ-BAUTISTA**, Instituto de Biología, Departamento de Zoología, Universidad Nacional Autónoma de México, Apartado Postal 70-153, México, Distrito Federal 04510, México.

HYDROPS TRIANGULARIS. PARAGUAY: Departamento Presidente Hayes: Río Paraguay ca. 14 km by river S from Puerto Rosario, 24°32'22"S, 57°10'15"W. 26 January 1995. E. Buongermini P., T. Waller, and P. Micucci. Museo de Historia Natural del Paraguay (MNHNP 06462). Verified by Marta Motte. First record for the Paraguayan basin. A male collected while crossing the river.

Submitted by **EMILIO BUONGERMINI P.**, Museo Nacional de Historia Natural del Paraguay, Sección de Herpetología, Caballero 1060, Asunción, Paraguay, CP 1324, and **TOMAS WALLER**, Zavalía 2090 3°B, Buenos Aires, Argentina, 1428.

LAMPROPELTIS CALLIGASTER RHOMBOMACULATA (Mole Kingsnake). USA: FLORIDA: Calhoun Co: near Blountstown. May 1996. C. J. Longden. Florida Museum of Natural History, University of Florida (UF Color Slide 111098). Verified by David Auth. New county record (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part One. The Snakes. Second Ed. Windward Publ., Miami, Florida. 176 pp.). Offspring from gravid female collected from wild. Laid 4 eggs 17 June; 3 eggs hatched 20 August 1996.

Submitted by **KENNETH L. KRYSKO**, Department of Wildlife Ecology and Conservation, University of Florida, Gainesville, Florida 32611, USA.

LAMPROPELTIS GETULA (Common Kingsnake) USA: COLORADO: Bent Co: DOR, Co. Rd. 24, 0.1 mi S jct Rt. 50. 16 August 1997. Verified by Hobart M. Smith and David Chiszar. University of Northern Colorado Museum of Natural History (UNC-MNH 765). County record (Livo et al. 1996. Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.). An additional specimen (UNC-MNH 611 from Otero County found DOR on Co. Rt. 109, 0.1 mi N jct Co. Rd. Y; 37°55.416'N, 103°32.403'W on 2 June 1997) was also recovered, confirming the natural presence of this species in Otero County. All specimens taken in eastern Colorado have been found south of the Arkansas River drainage. Specimen is intermediate between the races *holbrooki* and *splendida*.

Submitted by **ENOCH BERGMAN, CHAD MONTGOMERY, THERESA CHILDERS, JERRY D. MANZER, JAMES SIFERT, BEN HILL,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

LAMPROPELTIS GETULA (Common Kingsnake). USA: FLORIDA: Franklin Co: St. Vincent Island. An adult male collected on "Christman's Road" between roads 4 & 5. 18 May 1983. Steven P. Christman. UF 57740. Verified by David L. Auth. Another adult male was found on 12 April 1987 at the Picalene Indian midden (archaeological site 8FR365) on the Apalachicola Bay side of St. Vincent Island in NE 1/4 SE1/4 Sec. 20, T9S, R9W by D. Bruce Means, and was also verified by David L. Auth. Four 35 mm slides of this second specimen were catalogued together as UF 111442. First published records of species on any of the eastern Gulf Coast barrier islands of Apalachee Bay (Blaney 1971. Herpetologica 27:406–430).

Submitted by **D. BRUCE MEANS**, Coastal Plains Institute and Land Conservancy, 1313 North Duval Street, Tallahassee, Florida 32303, USA.

LAMPROPELTIS GETULA GETULA (Eastern Kingsnake). USA: FLORIDA: Bay Co: SR 22, ca. 17 mi W Wewahitchka. May 1997. C. J. Longden. Florida Museum of Natural History, University of Florida (UF Color Slide 109826). Verified by David Auth. New county record (Ashton and Ashton 1988. Handbook of Reptiles and Amphibians of Florida. Part One. The Snakes. Second Ed. Windward Publ., Miami, Florida. 176 pp.).

Submitted by **KENNETH L. KRYSKO**, Department of Wildlife Ecology and Conservation, University of Florida, Gainesville, Florida 32611, USA, e-mail: kenneyk@grove.ufl.edu, and **LEONARD E. KRYSKO**, 7575 128 Street North, Seminole, Florida 34646, USA.

LAMPROPELTIS GETULA SPLENDIDA (Desert Kingsnake). USA: NEW MEXICO: Lincoln: DOR U.S. Rt. 54 at Mile Marker 106, 46.7 km N Tularosa, ESE 1/4 Sec 36, T9S, R8. 27 August 1997. Doug Burkett. University of New Mexico Museum of Southwestern Biology (MSB 61000). Verified by D. S. Sias. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **DOUG BURKETT**, P.O. Box 399, White Sands Missle Range, New Mexico 88002, USA, and **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico 87504, USA.

LAMPROPELTIS TRIANGULUM (Milk Snake). USA: ARIZONA: Coconino Co: Aubrey Valley: 35°30'01"N, 113°07'35"W. 5 June 1997. Betsy Dunkirk. ASU 30876. Verified by Jeff Howland. Specimen found dead in two pieces next to Arizona Game and Fish Department Black-Footed Ferret (*Mustela nigriceps*) acclimation pen no. 6. First specimen from the Aubrey Valley; extends range ca. 90 km west from the nearest documented specimen in Coconino County (Jeff Howland, pers. comm.; George Bradley, pers. comm.). Supports previous observations of *L. triangulum* in this valley. Kim Kime reported (Arizona Game and Fish Department, Heritage Data Management System) seeing a ca. 60 cm long specimen near this locality on 21 July 1994 at 0345 h while spotlighting for Black-Footed Ferrets. Steve Campbell reports capturing a female specimen in the Aubrey Valley near the town of Seligman (Yavaipai County: SW 1/4 of NE 1/4 Section 4, T23N, R7W) on 11 July 1992, although this speci-

men has not yet been deposited in an institutional collection nor reported in the literature.

Submitted by **ANDREW T. HOLYCROSS**, Zoology Department, Arizona State University, Tempe, Arizona 85287-1501, USA, and **ROB SIMONSON**, Arizona Game and Fish Department, Nongame Branch, 2221 West Greenway Road, Phoenix, Arizona 85023-4312, USA.

LAMPROPELTIS TRIANGULUM (Milk Snake). USA: TEXAS: IRION CO: Barnhart. 22 May 1997. Jeff Wright. Angelo State Natural History Collections (ASNHC 12909). Verified by Terry C. Maxwell. New county record (Dixon 1987. Amphibians and Reptiles of Texas. Texas A&M Univ. Press, College Station. 434 pp.). Apparent intergrade between *L. t. annulata* and *L. t. celaenops*. The status of *L. triangulum* in this area of Texas is uncertain and deserves further investigation. The only known specimens that exist from this area are UTA 38339 from 8 km S of Barnhart in Crockett County and ANSP 26588 from San Angelo in Tom Green County. TNHC 7134 from Texon in Reagan County was collected in 1949 but reported lost in 1962. It is assumed that this snake was identified properly. Institutional acronyms follow Leviton et al. 1985 (Copeia 1985:802–832).

Submitted by **JERRY F. HUSAK**, Department of Biology, Angelo State University, San Angelo, Texas 76909, USA, and **JEFF WRIGHT**, 11633 Hawk Avenue, San Angelo, Texas 76904, USA.

LAMPROPELTIS TRIANGULUM GENTILIS (Plains Milk Snake) USA: COLORADO: CROWLEY CO: DOR, Rt. 96 2.9 mi W jct Co. Rd. 27 (38°14.499'N, 103°37.645'W). 2 June 1997. Verified by Hobart M. Smith and David Chiszar. University of Northern Colorado Museum of Natural History (UNC-MNH 582). County record (Livo et al. 1996. Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.).

Submitted by **ENOCH BERGMAN, CHAD MONTGOMERY, THERESA CHILDERS, JERRY D. MANZER, JAMES SIFERT, BEN HILL,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

LAMPROPELTIS TRIANGULUM GENTILIS (Plains Milk Snake) USA: COLORADO: BACA CO: AOR, NW corner Co. Rd. 45 and Co. Rd. 6 (37°04' 37.96"N, 102°16' 25.19"W). 11 May 1997. Adult pair found beneath tin. University of Northern Colorado Museum of Natural History (UNC-MNH Photograph 25). Southern range extension of ca. 25 miles (Livo et al. 1996. Herpetological Microbiogeography of Colorado II: Documented and Potential County Records. Publ. Colorado Herpetol. Soc.); LAS ANIMAS CO: live under log on side of Co. Rd. 18.2, 1.0 mi S jct Co. Rd. 193.7 (37°07.181'N, 103°17.975'W). 24 September 1997. UNC-MNH Photograph 26. Southern range extension of ca. 60 miles and a northern extension from New Mexico populations of ca. 50 miles (Livo et al. 1996, *op. cit.*). Both verified by Hobart M. Smith and David Chiszar.

Submitted by **CHAD MONTGOMERY, THERESA CHILDERS, ENOCH BERGMAN, JERRY D. MANZER, JAMES SIFERT, BEN HILL,** and **STEPHEN P. MACKESSY**, Department of Biological Sciences, University of Northern Colorado, Greeley, Colorado 80639, USA.

LIOTYPHLOPS TERNETZII. ARGENTINA: ENTRE RIOS: Department Colón: Parque Nacional El Palmar (Ubajay), 31°47'S, 58°18'W. 25 October 1984. Herpetological collection of Museo Argentino de Ciencias Naturales "Bernardino Rivadavia," Buenos Aires, Argentina (MACN 32922). Verified by G. Scrocchi. First province record for the genus (Vuoto 1995. Mem. Mus. Cs. nats. y antropol. Prof. A. Serrano, Serie Nueva Zool. N° 5:17 pp., E. Ríos) extends known range ca. 600 km S from previously cited localities (Bergna and Alvarez 1992. Facena 9:106; Giraudo 1994. Cuad. Herpetol. 8[2]:229-231).

Submitted by **SONIA KRETZSCHMAR**, Instituto de Herpetología, Fundación Miguel Lillo, Miguel Lillo 251, 4000 San Miguel de Tucumán, Argentina; e-mail soniak@unt.edu.ar.

MASTICOPHIS FLAGELLUM (Coachwhip). USA: NEW MEXICO: LOS ALAMOS CO: Los Alamos National Laboratory, 0.8 km W White Rock, 396510mN, 388610mE. 17 July 1997. Esther I. Nelson. University of New Mexico Museum of Southwestern Biology (MSB 61001). Verified by D. S. Sias. New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque. xix + 431 pp.).

Submitted by **ESTHER I. NELSON**, Los Alamos National Laboratory, P.O. Box 1663, M887, Los Alamos, New Mexico 87545, USA, and **CHARLES W. PAINTER**, New Mexico Department of Game and Fish, P.O. Box 25112, Santa Fe, New Mexico, 87504, USA.

MASTICOPHIS FLAGELLUM FLAGELLUM (Eastern Coachwhip). USA: KENTUCKY: PULASKI CO: Pulaski, 14 mi S [of Eubank] [DOR] on [Rt.] 27. 6 June 1948. Collector unknown. UMMZ 221630. Verified by Arnold G. Kluge. County record; third record for the state (Collins and Hirschfeld 1971. J. Herpetol. 5:193) and first record for eastern Kentucky (Conant and Collins 1991. Peterson Field Guide to Reptiles and Amphibians of Eastern and Central North America. Third Ed. Houghton Mifflin Co., Boston, Massachusetts. xviii + 450 pp.). Specimen was found in the personal collection of the late William Simpson of Detroit. The locality information in brackets was interpreted from a water and mildew damaged jar label. Specimen may have been collected by Jack Cody whose name was associated with some other specimens from Kentucky in the Simpson Collection. Specimen is a female, light phase with black pigment on the head and neck, SVL 1468 mm, with 205 ventral scales.

Submitted by **GREGORY E. SCHNEIDER**, Division of Reptiles and Amphibians, Museum of Zoology, University of Michigan, Ann Arbor, Michigan 48109-1079, USA.

MASTICOPHIS LATERALIS (Striped Racer). USA: CALIFORNIA: MENDOCINO CO: Rt. 162, 21.25 km NE (by road) of Rt. 101, rocky slope on the E side of the main stream of the Eel River. 11 October 1992. J. V. Vindum. CAS 186406; Rt. 162, 28.69 km NE (by road) of Rt. 101, rocky slope on the N side of Middle Fork Eel River. 3 September 1994. J. V. Vindum. CAS 196344. Both verified by R. C. Drewes. Second and third records from Mendocino County and first records from the Eel River drainage. Extends the range ca. 42 km N of MVZ 97839 (California: Mendocino Co: 16 km S of Willits), ca. 120 km S of westernmost Trinity County record (Lind 1992. Herpetol. Rev. 23:124), and ca. 65 km WSW of MVZ 193333 (California: Tehama Co: Round Valley Road, ca 0.4 km N Salt Creek Saddle). These new records occur W of the North Coast Range crest, which was thought to be a geographic barrier to the westward dispersal of the species in northern California (Bury 1970. J. Herpetol. 4:165–178).

Submitted by **JENS V. VINDUM**, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.

NERODIA SIPEDON PLEURALIS (Midland Water Snake). USA: MISSOURI: PERRY CO: 12.9 km E Perryville (37°45'46"N, 89°42'59"W). 15 October 1994. B. Churchwell, J. Krejca, and S. Taylor. SIUC R-2807. Verified by R. A. Brandon. Dead on paved road near pond, farm fields, and woodlots. County record; not previously reported in Missouri counties bordering the Mississippi River south of Ste. Genevieve County (Johnson 1987. The Amphibians and Reptiles of Missouri. Publ. Missouri Dept. Conserv., Jefferson City. 368 pp; Powell et al. 1993. Missouri Herpetol. Assoc. Newsl. 6:7–26).

PITUOPHIS CATENIFER SAYI (Bullsnake). USA: MINNESOTA: CARLTON CO: Split Rock Twp., 15 km W Moose Lake (SW 1/4 SW 1/4 Sec. 24, T46N, R21W). 12 September 1996. Leonard and Sandra Pasek. JFBM 13512. Verified by James Underhill. County record (Oldfield and Moriarty 1994. Amphibians and Reptiles Native to Minnesota. Univ. Minnesota Press, Minneapolis. 237 pp.) This extends the range ca. 100 km north.

Submitted by **JOHN J. MORIARTY**, Hennepin Parks, 3800 County Road 24, Maple Plain, Minnesota 55359, USA.

PSEUSTES POECILONOTUS POLYLEPIS. VENEZUELA: ESTADO ARAGUA: Municipio Girardot, La Pedrera, Tucupido. Parque Nacional Henri Pittier, 10°16'N, 67°31'W, 600 m elev. 1997. C. Linares. Museo del Servicio AutÛnomo PROFAUNA, Ministerio del Ambiente y de los Recursos Naturales Renovables, Maracay (EBRG 3340). Verified by R. Rivero. First record for state of Aragua and the Parque Nacional Henri Pittier, filling gaps between the state of Carabobo and the Distrito Federal (Manzanilla et al. 1996. Acta Cient. Venezuela 47[3]:1–12).

Submitted by **KAREL LEMOINE** Instituto de ZoologÌa Agrícola, Facultad de Agronomía, Universidad Central de Venezuela, Maracay, Venezuela, **GILSON RIVAS**, Museo de Historia Natural La Salle, Caracas, Venezuela, and **JESÚS MANZANILLA**, Museo del Instituto de Zoología Agrícola, Facultad de Agronomía,Universidad Central de Venezuela, Maracay, Venezuela.

RAMPHOTYPHLOPS BRAMINUS (Brahminy Blind Snake). USA: FLORIDA: SEMINOLE CO: Casselberry, ca. 3 km E jct Florida Rt. 436 and Oxford Road under a brick in backyard of residential home at 1516 East Boulevard. 27 March 1998. Douglas T. Bowman, Jr. and Richard D. Owen. Deposited in the Florida Museum of Natural History collection (UF112961). Verified by F. Wayne King and David Auth. First documented occurrence of species in county. Populations of this snake exist at numerous locations in southern Florida and they appear to have been established there via the exotic plant trade (Conant and Collins 1991. Peterson Field guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 450 pp.; Wilson and Porras 1983. The Ecological Impact of Man on the South Florida Herpetofauna. Univ. Kansas Mus. Nat. Hist. Spec. Publ. 9:1–89). Considering the widespread use of exotic plants in the Florida landscape, as well as the parthenogenic reproductive mode of the snake, we suggest that this observation be considered a range extension of the species. In the near future additional observations of the Brahminy Blind Snake will likely be made in the area between central and south Florida, and possibly in northern Florida as well.

90040-060, Porto Alegre, Rio Grande do Sul, Brazil

Examination of anuran specimens deposited in Coleção de Anfíbios do Museu de Ciências Naturais (MCN), of the Fundação Zoobotânica do Rio Grande do Sul, along with new material obtained in recent collections, deposited in Coleção de Répteis e Anfíbios of the Departamento de Zoologia da Universidade Federal do Rio Grande do Sul (UFRGS-DZ) and Museu de Ciências e Tecnologia da Pontifícia Universidade Católica do Rio Grande do Sul (MCP), revealed nine previously unrecorded species from the State of Rio Grande do Sul. It also allowed us to extend known ranges of three species for the state of Santa Catarina. Additionally, we correct the erroneous record of *Thoropa miliaris* for Rio Grande do Sul. Identifications were verified by José Perez Pombal, Jr., and Ulisses Caramaschi.

HYLIDAE

Hyla albopunctata. SANTA CATARINA: Canoinhas Municipality (26°10'38"S, 50°23'24"W, 834 m). 20 December 1994. P. C. A. Garcia. MCP 3114–17. RIO GRANDE DO SUL: Santo Antônio das Missões Municipality (28°30'41"S, 55°13'40"W, 213 m). 17 January 1977. T. O. Bocaccio. MCN 11706. There was no previous documented record for *H. albopunctata* in Rio Grande do Sul, even though de Sá (1995) provided a distribution map for the species which included northern Rio Grande do Sul.

Hyla caingua. RIO GRANDE DO SUL: Cruz Alta Municipality (28°38'19"S, 53°36'23"W, 452 m). 4 November 1975. T. Lema, A. Lise and S. Scherer. MCN 8883–84, 8886; Santo Antônio das Missões Municipality (28°30'41"S, 55°13'40"W, 213 m). 3 October 1989. P. C. Braun. MCN 13362; Panambi Municipality: Condor (28°17'33"S, 53°30'06"W, 418 m). 30 July 1997. G. Vinciprova. UFRGS-DZ 1683. These records extend known range of the species ca. 220 km SE from Depto. de Playadito, Province de Corrientes, Argentina, as reported by Carrizo (1990).

Hyla hylax. SANTA CATARINA: Florianópolis Municipality: Córrego Grande (27°37'00"S, 48°30'00"W, 100 m). 11 September 1990. P. C. A. Garcia. MCP 3122. 12 December 1990. P. C. A. Garcia. MCN 13430–1. 18 September 1991. P. C. A. Garcia. MCP 3120. 11 September 1992. P. C. A. Garcia. MCP 3121. These records extend the known range of the species ca. 240 km S from Paranaguá Municipality: Prainha, Paraná State, as reported by Heyer (1985b).

Hyla microps. RIO GRANDE DO SUL: Tenente Portela Municipality, Parque Estadual do Turvo (27°22'16"S, 54°54'01"W, 390 m). 24 June 1985. J. Pilla. MCN 1097, 1106, 1116. These records extend known range of the species ca. 200 km W from São Francisco de Paula Municipality, Rio Grande do Sul, as reported by Kwet (1998).

Hyla nahdereri. SANTA CATARINA: Campos Novos Municipality, Ibicuí River (27°34'30"S, 51°10'10"W, 934 m). 25–29 January 1989. T. Lema et al. MCP 892–5; Rancho Queimado Municipality (27°40'21"S, 49°01'18"W, 810 m). 11 October 1991. P. C. A. Garcia. MCN 13432–33. 11 October 1993. P. C. A. Garcia. MCP 3123–24. These records extend the known range of the species ca. 230 km SSW from the type locality (São Bento do Sul, Santa Catarina, Frost 1985), to which the species had been restricted.

Scinax rizibilis. SANTA CATARINA: Florianópolis Municipality, Córrego Grande (27°37'00"S, 48°30'00"W, 100 m). 27 January 1991. P. C. A. Garcia. MCN 13443–44, MCP 3134–37. RIO GRANDE DO SUL: Terra de Areia Municipality (29°35'07"S, 50°04'15"W, 14 m). 29 September 1995. G. Vinciprova. UFRGS-DZ 1678–82. These records extend known range of the species ca. 400 km S from Corupá, Santa Catarina, the type-locality of *H. mirim*, a junior synonym for *H. rizibilis* according to Andrade and Cardoso (1987).

Sphaenorhynchus surdus. SANTA CATARINA: Lontras Municipality (27°09'58"S, 49°32'31"W, 330 m). 21 February 1991. P. C. A. Garcia. MCP 1302–05. Lages Municipality (27°48'58"S, 50°19'34"W, 884 m). 19 December 1995. A. Cardoso, P. C. A. Garcia and G. Vinciprova. UFRGS-DZ 1626–27; Tubarão Municipality (28°28'00"S, 49°00'25"W, 9 m). 10 December 1986. T. Lema and M. Di Bernardo. MCN 1325. RIO GRANDE DO SUL: São Pedro de Alcântara Municipality: (29°20'07"S, 49°43'37"W, 16 m). 29 December 1977. P. C. Braun and C. A. S. Braun. MCN 11929–30, MCN 12028–31. These records extend known range of the species ca. 600 km SSW from the type locality (Curitiba Municipality, Paraná, Frost 1985).

Phyllomedusa distincta (Perereca-da-Folhagem). RIO GRANDE DO SUL: Terra de Areia Municipality (29°35'07"S, 50°04'15"W, 14 m). 15 December 1995. G. Vinciprova and A. J. Cardoso. UFRGS-DZ 1621. 25 september 1997. G. Vinciprova. UFRGS-DZ 1684. These records extend the known range of the species ca. 150 km S from Lauro Müller Municipality, Novo Horizonte, Santa Catarina, as reported by Pombal, Jr. and Haddad (1992:228).

CENTROLENIDAE

Hyalinobatrachium uranoscopum (Rã-de-Vidro). RIO GRANDE DO SUL: Planalto Municipality (27°19'44"S, 53°03'31"W, 568 m): Rio do Mel. 19 January 1994. G. Vinciprova. UFRGS-DZ 1392; Planalto Municipality: Rio do Mel. 20 January 1994; Planalto Municipality: Rio do Mel. G. Vinciprova. UFRGS-DZ 1456; Planalto Municipality. 23 January 1994. G. Vinciprova. UFRGS 1465–66. 14 March 1997. These records extend the known range of the species ca. 170 km SE of San Antonio Depto., Misiones Province, Argentina, and 350 km W from Lauro Müller Municipality, Santa Catarina, as reported by Heyer (1985a).

LEPTODACTYLIDAE

Leptodactylus chaquensis. RIO GRANDE DO SUL: Bossoroca Municipality (23°43'48"S, 54°54'01"W, 228 m). 7–11 January 1972. P. C. Braun and I. J. Borowski. MCN 4500–07. São Vicente do Sul Municipality (29°41'30"S, 54°40'46"W, 129 m). 30 November 1981. MCN 12790. M. I. Vieira. Uruguaiana Municipality (29°45'17"S, 57°05'18"W. 66 m). 8 November 1973. E. Huber. MCN 5484–91. Uruguaiana Municipality: Touro Passo. February 1974. Miguel Bombim. MCN 6745–46. These records extend the known range of the species ca. 100 km E from Misiones Province, Argentina (Cei 1987) and 170 km NE of Artigas Depto., Uruguay (Vaz-Ferreira et al. 1984).

Eleutherodactylus binotatus (Rã-da-Mata). RIO GRANDE DO SUL: São Pedro de Alcântara Municipality (29°20'07"S, 49°43'37"W, 16 m). 21 February 1966. T. Lema. MCN 4158. This records extends known range of the species ca. 200 km S from Florianópolis Municipality, Santa Catarina, as reported by Garcia (1996).

Cyclorhamphus valae. RIO GRANDE DO SUL: Cambará do Sul Municipality: Fortaleza dos Aparados (29°02'52"S, 50°08'41"W, 1031 m). 6 January 1976. P. C. Braun et. al. MCN 9956. This record extends known range of the species ca. 90 km SW from type-locality (Gruta, Lauro Müller Municipality) as reported by Heyer (1983).

Thoropa saxatilis (Rã-das-pedras). RIO GRANDE DO SUL: Cambará do Sul Municipality, Fortaleza dos Aparados (29°02'52"S, 50°00'41"W, 1031 m). 6 January 1976. P. C. Braun. MCN 9717–18; Cambará do Sul Municipality, Itaimbezinho. 21 December 1976. S. Scherer and A. Lise. MCN 11705; Cambará do Sul Municipality. 12 January 1978. P. C. Braun, C. A. S. Braun and J. Rodrigues. MCN 12250. The possibility of occurrence of *T. saxatilis* in Rio Grande do Sul was already mentioned by Cocroft and Heyer (1988), who argued that *T. miliaris* could have been misidentified by Braun and Braun (1980). We confirm that specimens mentioned by Braun and Braun in fact belong to *T. saxatilis*. *Thoropa miliaris* should be removed from the species list of anurans for Rio Grande do Sul.

Acknowledgments.—We thank Christine Strussmann for reviewing this manuscript, and FAPERGS for a fellowship to P. C. A. Garcia.

So much of the earth is now affected by human activities that greater investigative efforts will have to be directed toward disturbed habitats. Study of these newly formed "ecosystems" is necessary for understanding the dynamics of novel species assemblages as well as pollutant-organism interactions. Herein we report on the herpetofaunal populations in and around Onondaga Lake, considered among the most polluted lakes in North America (Effler and Hennigan 1996).

Onondaga Lake lies on the northwestern corner of the Syracuse urbanization area (population ca. 390,000), Onondaga County, central New York State, USA, and is surrounded by urban industrial and commercial sites and residential communities. The Onondaga Lake ecosystem was operationally defined as those aquatic, wetland, and terrestrial habitats in and around the lake up to a maximum of 250 m from the lake shorelines. Thus defined, the ecosystem is bounded on all sides by major highways and thoroughfares which are probably effective barriers to herpetofaunal terrestrial dispersals. Water enters the lake from six creeks and the Syracuse Metropolitan sewage treatment facility. Water leaving the lake enters the Seneca River of the Lake Ontario drainage system. The terrestrial habitats around the lake are largely parkland, old field, and deciduous forests over industrial waste beds, construction fill, or dredged lake sediment material (Effler and Hartnett 1996; VanDruff and Pike 1992). Several small wetlands, some connected to the lake, are scattered among the terrestrial areas.

The lake has a 150-year history of municipal and industrial pollution (Effler and Harnett 1996; Effler and Hennigan 1996).

TABLE 1. Amphibian and reptile species in the Onondaga Lake ecosystem, 1994–1997. * = less than three individuals found in four years of surveys. Catalog numbers are for voucher specimens or slides from Bowers Natural History Museum, SUNY Cortland.

Species	Life history stage	Voucher numbers
Bufo americanus	adult, calling males	96-101
Hyla chrysoscelis/H. versicolor	adult	96-110
Pseudacris crucifer	adult, juvenile	96-111
Rana clamitans	adult, larvae, juvenile	96-102
Rana pipiens	adult, larvae, juvenile	96-103
Ambystoma maculatum	adult, larvae	96-106
Notophthalmus viridescens	aquatic adult*	96-107
Nerodia sipedon	adult, gravid female	97S-11
Storeria dekayi	adult, neonate	96-104
Thamnophis sirtalis	adult, neonate	96-105
Chelydra serpentina	adult, egg	96-109
Chrysemys picta	adult, egg	96-108
Sternotherus odoratus	adult*	

Municipal sewage effluent and industrial discharge have been released into the lake since the mid-1800's (Effler and Hartnett 1996). By the late 1960s, 2.5×10^6 kg of ionic materials and 10 kg of mercury per day were being released into the lake by its single largest neighboring industry (Effler 1987). These releases were stopped by 1988, but the sewage and other industrial releases have continued. Today the lake's sediments and water column contain elevated levels of heavy metals (especially Hg), benzenes, chlorinated benzene compounds, polycyclic aromatic hydrocarbons, nitrites, and ammonia (Becker and Bigham 1995; Effler and Hennigan 1996; Normandeau Associates 1996; Wang and Driscoll 1995).

Studies of the vertebrates of the Onondaga Lake area have been limited, with the bulk of the work focused on gamefishes (Effler 1996; Tango and Ringler 1996; VanDruff and Pike 1992). There have been no previous surveys of the herpetofauna of this site.

We surveyed the lake ecosystem for herpetofauna from May 1994 through August 1997 using a combination of field techniques. We searched transects and quadrats throughout the ecosystem and used a form of time-constrained searching (termed select point sampling) in all terrestrial habitats over all seasons. For aquatic sampling we used dip-netting transects and trapping arrays using metal minnow traps and hoop turtle traps. Aquatic sampling was done in the lake and all other wetlands within the ecosystem. Auditory monitoring was conducted for all wetlands in the spring and summer of each year.

We found seven species of amphibians and six species of reptiles in the ecosystem (Table 1). This is considerably less than the nineteen amphibian species and fifteen reptile species recorded for Onondaga County as a whole during 1990–1996 (NYSDEC 1997). The species in the Onondaga Lake ecosystem are generally those most commonly reported across New York State (NYSDEC 1997) with a few notable exceptions. *Plethodon cinereus,* the most widely reported salamander in New York and usually the most abundant locally (PKD, pers. obs.), is absent from the terrestrial habitats surrounding the lake. The second most widely reported salamander in New York, *Notophthalmus viridescens,* although often in dense populations in farm ponds and disturbed areas, was extremely rare in the wetlands near Onondaga Lake. *Rana catesbeiana, R. sylvatica, Eurycea bislineata, Lampropeltis triangulum,* and *Storeria occipitomaculata* are widely distributed and locally abundant in central New York, and are generally tolerant of disturbed habitats, but were not found within this ecosystem.

Voucher specimens and/or slides for each species except *Sternotherus odoratus* are deposited in Bowers Natural History Museum of SUNY Cortland.

Acknowledgments.—This study was supported by grants (to PKD) from the U.S. Environmental Protection Agency, administered through the New York State Department of Environmental Conservation and the Onondaga Lake Cleanup Corporation, and the SUNY at Cortland Faculty Research Program. Numerous students at SUNY at Cortland aided in surveying efforts. Alvin Breisch and John Ozard provided data from the New York State Amphibian and Reptile Atlas.

This is a great time to be studying snakes. In addition to increasing recognition that snakes make good "model organisms" for many kinds of ecological and evolutionary studies, snakes are receiving long-overdue attention in the form of detailed book-length reviews and monographs. Although many current graduate students may not realize it, this is a major change from the not-too-distant past. When we first began working with snakes in 1979, the major review works available as an introduction to snake biology were Parker and Grandison's *Snakes: A Natural History*, Wright and Wright's *Handbook of Snakes*, and, of course, Klauber's epic two-volume *Rattlesnakes*. Although these were (and are) great books, they were either too limited in scope or too out-of-date to be of much use for graduate students looking to get "jump started" on snake ecology and evolution.

Things have really changed today. In addition to a number of recent edited or multi-authored volumes on snake ecology, evolution, and behavior (mainly targeted at professionals), we now have two terrific single-author volumes intended for a broader audience: Rick Shine's *Australian Snakes: A Natural History* (1991), and Harry Greene's *Snakes: The Evolution of Mystery in Nature* (1997), the subject of this review.

Greene's book is an oversized, 351-page volume that attempts to appeal to a wide audience, from the professional to the interested layperson. The book is divided into three major sections. Part One: Lifestyles, is a 153-page overview of snake biology and evolution, with material that will interest the biologist and the sophisticated layperson alike. Part Two: Diversity, is a 110-page family by family review of snake diversity and taxonomy. Much of the text is fascinating for snake biologists, but may be of limited interest to the general public. Part Three: Synthesis, is the shortest section of the book, and comprises a 40-page discussion of snake evolution, biogeography, a brief biography of some past workers on snake biology, and a short overview of snake conservation and management. We do wish the last section had been longer, especially in convincing the public for the need for appropriate protection for snake biodiversity. Interspersed among these sections are 13 short essays on "Special Topics," which range from "Deadly Colubrids and Famous Herpetologists" to "The Coralsnake Mimicry Problem." These short essays were generally very entertaining and most will be highly interesting to the layperson.

The utility of any book can be judged on three criteria: the quality of the information presented, the quality of the writing, and the quality of the presentation. We judged this book on two levels: one from the view of the professional herpetologist, the other from the viewpoint of a non-specialist educator who happens to enjoy snakes. From both of our viewpoints, this book rates as "outstanding" in all three of the above criteria. Greene's writing style ranges from warm anecdotes regarding snake studies in the field (our favorite being his detailed account on how to **try** to catch a coachwhip), to concise summaries about what we know (and don't know) about snake biology. We were especially impressed by the clear and entertaining visualization of how snakes manage to eat very large prey on pp. 55 and 59. The only area that we felt was weak was the introduction to phylogeny and taxonomy on pp. 13–17, which one of us (NAS) felt was rather confusing for non-biologists.

The information content of this book is top-notch, and will prove an essential reference for herpetologists and other biologists interested in snakes. Even those actively engaged in research on snakes will find highly useful reviews of snake phylogeny, evolution, feeding, and behavior. If you are a graduate student in herpetology, you should run, not walk, to your nearest computer and order this book from the appropriate electronic bookstore. (We found a 30% discount on one Web site we checked.)

No review of this book could be complete without mentioning the photographs. Executed by Michael and Patricia Fogden, they are nothing less than stunning. Although this is far from a "coffee-table" book, you could easily leave this book out for your dinner guests for their delight and edification. If you can repeat some of Greene's stories about the behavior of some of the many rare and unusual species illustrated in the text, your reputation as a naturalist is bound to be inflated among your friends and family.

Criticisms are an expected part of a book review, but we were hard-pressed to find many substantive ones. The book seems well constructed, the text is legible (although a bit small), the index and table of contents both work well, and the price is terrific (especially for a book with so many color plates). Several minor points should be mentioned. First, we wished that the references had been in the text, rather than summarized in the back of the book. Although this may make the text slightly more accessible for the general public, it reduces the book's utility for the professional community by a small degree. The references were, however, extensive and complete. Second, the absence of a glossary was a notable flaw, especially in a book targeted at least partially for the non-specialist. Although some complex systematic terms are defined in an appendix, a concise list of biological terms seems essential in a book such as this. Perhaps this could be corrected in a revised edition. Third, the book was somewhat lacking in diagrams and line drawings; the same section on feeding that we praised above was also a bit confusing when Greene discusses skeletal systems; a line drawing would have helped a lot.

Comparisons between Greene's book and Rick Shine's text on the natural history of Australian snakes are perhaps inevitable. Both are superb products from two of the outstanding snake biologists of their time and appeal to much the same audience. However, choosing between the two is fruitless; both should be on the bookshelf of anyone interested in snakes. Perhaps the most striking contrast between the two texts concerns their respective attitudes towards venomous snakes. On p. 215 of Greene's book he states that "big elapids are among the scariest of animals." We agree wholeheartedly, but our conversations with Shine suggest that he would concur only if you replaced the word "elapids" with "rattlesnakes"!

In summary, this is a great book, and will stand as a long-lasting tribute to Harry Greene's broad accomplishments in herpetology. You will want a copy on your bookshelf, a copy for your graduate students, and we suspect you will find it an invaluable reference for lecture classes as well.

Herpetology, by F. Harvey Pough, Robin M. Andrews, John E. Cadle, Martha L. Crump, Alan H. Savitzky, and Kentwood D. Wells. 1998. Prentice Hall, Upper Saddle River, New Jersey. 577 pp. Hardcover. US $72.00. ISBN 0-13-850876-3.

AARON M. BAUER

800 Lancaster Avenue, Villanova, Pennsylvania 19085-1699, USA
e-mail: abauer@king-kong.vill.edu

Despite what we would like to think, herpetology as an academic discipline is still a small field. Unlike general biology, genetics, biochemistry, or introductory ecology, the demand for textbooks is limited and the market is unlikely to support a diversity of competing titles. Until this year the only available herpetological textbook in English has been that by Zug (1993), which in turn replaced earlier texts by Goin, Goin, and Zug (1978), Porter (1972), and Goin and Goin (1962). It is certainly true that a larger, more well-illustrated, up-to-date herpetology text was sorely needed, and *Herpetology* does fit the bill. Nonetheless, I have a very mixed reaction to this contribution from Pough and colleagues. The book achieves its major aims, and will be used by herpetology classes around the country, but it is rife with errors and lacks the tight editorial supervision demanded by a book with six authors. The errors themselves would be excusable if they were errors of omission (after all, we each have our own views about what topics and examples are essential), but many of the errors in this text are errors of commission and, as such, they provide misinformation to novice readers (i.e., students).

Herpetology is organized into four sections: "What are amphibians and reptiles?", "How do they work?", "What do they do?", and "What are their prospects for survival?" The first section deals mainly with the basic anatomy, systematics, evolution, diversity, and distribution of amphibians and reptiles. It also includes an introductory chapter on herpetology as a discipline. The second section treats physiology, reproduction, and functional morphology. The third section covers behavior and ecology, and the fourth contains only a single chapter dealing with conservation, a topic that must be addressed in any modern herpetology course. Each chapter concludes with a summary. These are highly variable in level of detail, with some providing useful overviews and others being too sketchy to really serve a function. Overall, the authors present a fairly comprehensive overview of herpetology and I was not struck by many glaring omissions of topics or concepts (but see below). However, the interests of at least some of the authors are reflected in the depth of coverage of certain fields and in the apparent non-random distribution of errors, typos, and editing rigor. There are also a few quirks in the organization of material within the book. For example, there are two sections dealing with the structure and function of pit organs. Oddly, the longer section is not listed under "Pit organs" (p. 303), but rather on p. 111 under the sensory systems subsection in the general section on snakes. Perhaps most confusing, a section on "Pets and Zoo Exhibits" in the last chapter says nothing about zoo exhibits.

My own interests in systematics, biogeography, and morphology perhaps make me more acutely aware of errors in the first section of the book than in others, and perhaps I am being too picky, but I noted more than 100 factual errors (each relatively small) in this section of the book. The remainder of the book was less striking in this regard, although typographical errors, the use of outdated names and other evidences of editorial slack, are liberally sprinkled throughout the text. I am especially troubled by those errors relating to taxonomy and distribution. While such trifles may be regarded as of minor concern with respect to broad conceptual issues, they are among the many bits of factual information that we require our students to know and which distinguish amphibian systematists and reptile ecologists from those asking purely theoretical questions in the same conceptual disciplines.

Some of the difficulties with taxon names can be attributed to simple typographical errors (e.g., *Ichtyophis* for *Ichthyophis*, p. 47; *Rhotropus* for *Rhoptropus*, p. 98; *Basiliscus basilicus* for *B. basiliscus*, p. 395). Others reflect the use of outdated names (e.g., *Gerrhonotus multicarinatus* is used instead of *Elgaria multicarinata* in a figure caption, p. 104; *Heteropholis* is used instead of *Naultinus* for the South Island, New Zealand green geckos, p. 98; *Amphibolurus ornatus* is used rather than *Ctenophorus ornatus*, pp. 177, 202; a cladogram reproduced from an older source shows the family Polychridae rather than the Polychrotidae, p. 318; *Aporosaura anchietae* [misspelled as *anchiatae*] is used in place of *Meroles anchietae*, p. 138), or in many cases, the same species is cited under two different names, suggesting that the names were employed as they were used in the primary literature without a uniform attempt to standardize and update them (e.g., a diagram is labeled *Trionyx spiniferus* rather than *Apalone spinifera*, on p. 143, although the latter name is found in a figure legend on p. 81; *Trachydosaurus rugosus* and *Tiliqua rugosa* are both used in the text and indexed separately; *Tropidonotus natrix* is used instead of *Natrix natrix* on p. 184, although the name in current use appears at least four other places in the text). In still other instances, species are wrongly assigned to genus or even to family (*Trionyx triunguis* is listed as *Apalone triunguis*, p. 171; *Gallotia stehlini* is referred to the Agamidae rather than the Lacertidae, p. 413; *Hyla kivuensis* is used for *Hyperolius kivuensis*, p. 142). Finally, a variety of incorrect statements result from higher order taxonomic changes that were obviously incorporated into the familial summaries, but whose ramifications for other parts of the text were not considered. Chief among these are the recognition of the Eublepharidae as distinct from the Gekkonidae, and the recognition of several families of pleurodont iguanians. The terms gekkonid and iguanid thus are sometimes used to refer only to the more restricted families recognized by the authors and sometimes to the more inclusive groups of limbed gekkotans and pleurodont iguanians, respectively. Thus, *Coleonyx* is referred to as a gekkonid rather than a eublepharid (p. 314), the herbivorous specializations of iguanines (pp. 304–5), meaning the group introduced earlier (p. 94) as the Iguanidae, are discussed and *Uma* is listed as a member of the Iguanidae (p. 244), whereas it is elsewhere (p. 257) correctly assigned to the Phrynosomatidae.

Many errors have also crept into the written statements of distribution and especially into the printed maps. I applaud the use of maps showing country boundaries. These help the reader to more clearly pinpoint the edges of ranges and allow a more accurate comparison with more detailed physical or political maps should one be so inclined. However, having gone to the trouble of preparing such useful maps, the authors have used outdated base maps (they illustrate a united U.S.S.R. and Czechoslovakia and a divided Germany) and they have made numerous errors with respect to plotted ranges. One of these, showing the distribution of gekkonids in the Caspian Sea, is obviously an oversight, but others deserve some comment.

According to the maps provided, sirenids are endemic to the United States, as their distribution in northeastern Mexico is not

plotted. The illustrated distribution of salamandrids in South Asia does not extend far enough to the west to encompass the entire Indian range of *Tylototriton verrucosus*, nor does it include northern Iraq, where *Neurergus* and several other taxa occur. The map for pipids excludes most of Namibia, although *Xenopus laevis* is common in most of the permanent waters of the country, including desert springs. That for bufonids suggests a complete absence of this group in North Africa, where seven species of toads occur. It also does not extend far enough north in central Canada to encompass the true range of *Bufo hemiophrys*. Pelomedusids are not mapped in southwestern Africa where the genus *Pelomedusa* is extremely common. The map for the Trionychidae excludes the Philippines, New Guinea, the Horn of Africa, and Angola (essentially the distributions of *Pelochelys* and *Trionyx*). Agamids are omitted from Greece and portions of Mongolia and the southern parts of Asian Russia. Among iguanids, the distribution of *Brachylophus* in Fiji is mapped, but that in Tonga is not. The gekkonid map omits northern Mexico, California, and Florida, as well as large areas of the Palearctic range of the family. Eublepharids are illustrated as absent from western peninsular India, most of Iran, Kenya, and mainland China and Vietnam where they occur (although the last two localities are recent discoveries and cannot reasonably have been expected to appear on the maps). Varanids are not shown as occurring in much of their Asian range. Scincids are not depicted in the Caucasus or the Russian far east. Likewise, their North American distribution is also incorrect, with the range of *Eumeces septentrionalis* in northern Minnesota, southern Manitoba, and North Dakota largely excluded. Anguids are not illustrated as occurring in the inland of California (nor in western Nevada, where they have recently been recorded). The boid genus *Candoia* extends further into the Pacific than indicated on the corresponding map on page 119, reaching the Tokelau Islands. The mapped distribution of viperids in southwestern Canada is too restricted; in Alberta *Crotalus viridis* extends to almost 52° N. Elapids are incorrectly shown as absent from much of Peru.

In some cases the maps and written description of distribution do not match: The text for the Scolecomorphidae (p. 51) mentions Cameroon, Malawi, and Tanzania, whereas the map excludes Malawi but also illustrates the family's occurrence in Mozambique and Nigeria. Likewise, pygopodids are not mapped as occurring in New Guinea, where two species, one endemic, actually occur, although the text on this point is correct (p. 99). *Laticauda crockeri* is not, as indicated on page 126, restricted to freshwater lakes in the Philippines, rather it occurs on Rennell Island in the Solomons.

Additional errors plague other portions of the book as well. My own favorite group of herps, the Gekkota, is hit fairly hard with inaccuracies. The squamate phylogeny presented represents the Gekkonidae, Pygopodidae, and Eublepharidae as an unresolved trichotomy. I know of no systematist who would not regard the Eublepharidae as the sister group to the others. On page 92 gekkonids but not eublepharids are mentioned as having temperature-dependent sex determination (TSD), although the most well studied lizard in this regard is the eublepharid *Eublepharis macularius*. Elsewhere *Gekko* is singled out as an example of a gekkonid exhibiting TSD. This is true for some members of the genus but sex chromosomes have been identified in at least one species of *Gekko*. Gecko setae are mentioned as being 60–90 microns in length. Such long setae characterize only some groups of geckos, with most species having much shorter structures. The genus *Rhacodactylus* is stated to be viviparous, when in fact only one species of six, *R. trachyrhynchus*, is. *All* geckos are cited as having autotomic tails [note that the italics here and throughout the review are mine]; *Nephrurus asper* does not. The description of another defensive strategy, regional integumentary loss, is also incorrect. Contrary to the book's description, the whole skin is not lost, the morphological adaptation to the loss is in the dermis, not the epidermis, and the skin takes many months to regenerate, although fibroblasts cover the wound site rather quickly. Likewise, contrary to the text on page 428, the tail-squirting mechanism in *Diplodactylus* (*Strophurus*) does not involve the use of hollow spines as conduits of the secretion. Sphaerodactyls are known to have arisen within gekkonines; thus, the recognition of the Sphaerodactylinae on page 98 creates a paraphyletic group. Finally, there are six, not five, eublepharid genera, all of which lack spectacles (on page 107 eublepharids are listed as having spectacles, whereas gekkonids are not).

Such problems are not limited to geckos, however. They begin with the origin of tetrapods (three living lungfish species are stated to exist—there are actually six, p. 24), continue through amphibians (*Karaurus sharovi*, a well-known Jurassic salamander, is stated to be from Russia, p. 38—it is in fact from Kazakhstan), and on to reptiles (*all* cordylids, except *Cordylus giganteus*, are described as rock-dwelling, p. 105—in fact *Cordylus macropholis* is associated with vegetation and *Chamaesaura* spp. are grassland inhabitants). Many of the other misstatements in the text are contradictory and are clearly evidence of lack of critical editing. On page 111 it is stated that there are more than 1800 snake species, although elsewhere the more reasonable number of 2700 is given. On page 125 there are "approximately 70 species of sea snakes," while on page 126 only 60 species are acknowledged. In the chapter on reproduction, figure 7-1 shows a stylized *Cnemidophorus* as the representative of gynogenetic reproduction whereas an ambystomatid is illustrated to represent parthenogenesis. This is in contrast to the (correct) attribution in the text of parthenogenesis to reptiles and gynogenesis (or perhaps hybridogenesis, or both) to ambystomatids. A statement on p. 125 that "species of the *Hydrophis* group have lost the one-to-one association of ventral scales with vertebrae" appears to contradict that on p.112 that "the 1:1 relationship between ventral scale rows and vertebrae, characteristic of *all* other snakes, does not hold in Typhlopidae and Anomalepididae."

Several other comments reflect over generalizations or exaggerations. For example, contrary to the statement that *nothing* is known of the natural history of *Osteolaemus*, there exist basic (though limited) data on reproduction, diet, and other life history parameters. Likewise, the statement that "*all* scleroglossans use some visual displays in aggressive and courtship interactions" (p. 363) is without firm basis. Vocal signals are not limited to gekkonids, as claimed by the authors (p. 364), although they may be the only squamates to produce complexly modulated calls. There are exceptions to the statement (p. 241) that metatarsals I–IV in lizards are tightly bound, specifically in geckos, in which the feet exhibit a secondary symmetry.

Still other statements, while true, may be confusing to the uninitiated. On page 113 the enlarged quadrate of leptotyphlopids is referred to as part of the lower jaw. Although it functions in the movement of the mandible, the quadrate forms the distal part of the upper jaw articulation and students who may remember their comparative anatomy may be stymied by this interpretation. The term chondrocranium is used to mean larval skull (p. 272). This is not the general use of the term which is typically applied to the endochondral portion of the skull except the visceral (or splanchnocranial) skeleton. The usage here includes both the chon-

drocranium and splanchnocranium and implies that the term applies during only the larval life stage. On page 231 it is stated that the lack of maxillary bones yields a pointed snout in *Necturus*. It should be clarified that the skull is pointed, but that the snout as a whole is definitely not. The presence of sonograms with no corresponding discussion of how to "read" them, and the discussion of physiological parameters without an explanation of the units involved may also prove to be difficulties for students who have not had courses in associated disciplines.

The production values of the book are generally high, typical of modern, expensive textbooks, although several of my colleagues have noted dissatisfaction with the thinness of the paper (photos and even text tend to show through pages), and the quality of the binding (like most textbooks it is low but serviceable). Photo and figure reproduction are generally good, but there are notable exceptions. Some figures taken from other sources did not reproduce well and probably should have been redrafted or reproduced by other means. In particular, those illustrating the morphology and mechanics of fossorial reptiles (pp. 258–259) and the feeding of a larval ambystomatid (p. 268), are problematic. Many problems are associated with the figure captions. Some figures from the primary literature were apparently relabeled, resulting in errors in the textbook that are not present in the original (e.g., p. 335). The skull diagrams of snakes (pp. 115–117) lack a legend to the many abbreviations used as does the series of diagrammatic tadpole cross-sections on page 277. The reptile heart diagrams on page 183 have some, but not all, of the abbreviations explained. Contrary to the caption accompanying the illustration of a gila monster on page 300, the grooves in the teeth of the lower jaw are not illustrated. A photograph of the Cuban crocodile bears the caption "*Crocodilus rhombifer* (Crocodylidae, Australia)" thus including a generic misspelling and allocation to the wrong continent.

The litany of minor faults listed above could, for the most part, be dealt with by a detailed errata sheet. On the level of broader issues and topics in *Herpetology*, I am disappointed with one major omission. The book's discussion of distribution is almost exclusively ecological. Historical factors are mentioned, but there is no historical biogeographic framework for explaining amphibian and reptile distributions. Thus, distributions are presented more as disparate facts rather than as a unified record of earth and biotic spatial history. Indeed the terms biogeography, zoogeography, tectonics, or vicariance do not appear in the index and are effectively absent from the text. There is also little information about extinct lineages of amphibians and reptiles, although these are often treated, at least in passing, in herpetological courses. In particular, most students have an interest in dinosaurs and some placement of these and other extinct lineages into broader phylogenetic and functional frameworks would probably be appreciated. Other omissions are more a matter of taste and personal preference, although I would have liked to have seen a more detailed treatment of venoms and a review of basic tadpole mouthpart terminology, and among the topics that might have been mentioned in the section on feeding and diets are the many nectivorous lizards and their potential role in pollination, and the existence of herbivory in at least one frog species.

Finally, the book is provided with a bibliography of over 1500 references, many as recent as 1997. The authors state clearly in the preface that the references are biased towards more recent and accessible literature. This is a practical goal and one that is met reasonably well. However, if students are to use the references as an entrée into the literature it is somewhat troubling to find that foreign language citations are few and that there are no senior author citations for leading herpetologists like Mertens, Darevsky, and Lanza, whereas there are 51 such citations for the papers by the authors of the textbook.

My specific complaints aside, I am loathe to discard the baby with the bath water and do feel that Pough et al. have done a service to the discipline in producing an up-to-date herpetology text. I acknowledge the tremendous effort that has gone into this volume and merely wish to note that the final product has perhaps emphasized the forest at the expense of the trees. There is clearly room for improvement and much tighter editorial control in subsequent revisions. Nonetheless, the most important question regarding any textbook is "should I adopt it for class use?" The answer in this case is a qualified yes. The shortcomings of *Herpetology* do not outweigh the benefits of being able to offer students an extensively illustrated and up-to-date course text. Nonetheless, I would not be comfortable assigning this book to my students without providing them with an errata sheet and redrafted maps. The fact of the matter is that "-ology" courses are a combination of major themes and concepts and a lot of nuts and bolts details, the type that are necessary in order for students to gain a comfortable working background with the organisms. I would hope that the authors and Prentice Hall would consider a corrected second edition of the book at the earliest possible date, even if major updates and additions are not contemplated in the near future.

ULRICH JOGER

Hessisches Landesmuseum
Friedensplatz 1, 64283 Darmstadt, Germany
e-mail: u.joger@hlmd.tu-darmstadt.de

Wolfgang Böhme stated in his foreword to *Amphibians and Reptiles of North Africa* by Schleich et al. that "in northern, i.e. palearctic Africa, a herpetological field guide is lacking so far." As it is always more informative if book reviews can be done in a comparative way, it is fortunate that this is not entirely true. First, a fieldguide to Saharan herps and fishes was published by LeBerre

in 1989. Second, Bons and Geniez have produced a new "biogeographical atlas" of the amphibians and reptiles of Morocco that is a direct competitor to Schleich et al.'s book, as it covers 11 of the 12 amphibian species and 93 of the 110 reptile species of Schleich et al.'s more geographically inclusive book. In fact, as a field guide for the non-specialist, the atlas of Bons and Geniez is more useful as it depicts every single species (except the extralimital *Acanthodactylus savignyi*) in a good color photograph whereas Schleich et al., although presenting a great many more or less detailed drawings, depict only about two-thirds of the species photographically, and the quality of these figures varies considerably. Some specimens were dead when shots were taken. Others are represented by extralimital specimens (e.g., *Blanus cinereus*, *Coronella girondica,* and *Vipera latastei* from Spain) or even different species (e.g., *Leptotyphlops cairi* for *L. macrorhynchus* in Fig. 117, an Asian *Echis carinatus* in Fig. 145). It is especially regrettable that less than half of the endemic species and only five of 15 southern Saharan species are illustrated in color. However, Schleich et al. include keys for all genera, whereas the 'atlas' regrettably lacks these.

Amphibians and Reptiles of North Africa is devoted to the herpetofauna of Morocco, Algeria, Tunisia, and Libya, with Egyptian species listed in an appendix. The book is made up of a general part and a species section. The general part is subdivided into an introduction, a general species list (not complete, see below), a description of climate and vegetation, a large zoogeographical section, including a number of transects showing species community change and a country-based list of species numbers per genus (not complete, see below), an equally extensive ecological section with tables on habitat choice, seasonal activity and reproduction cycles, population density and biomass, and transects through selected habitats. This general part, making up some 90 pages, contains a wealth of information. However, it is very difficult to review the extensive tables in detail, as they accumulate data from different authors without giving references.

The rest of the book consists of the species accounts. When available, the authors try to present details about morphology, ecology, behavior, habitat, activity pattern, population structure and dynamics, ecological parameters (community, prey, predators), reproduction, distribution and systematics. Schleich et al. obviously have tried to incorporate as much available information on each species as possible. As a consequence, the account of a well known species, *Uromastyx acanthinura,* occupies 13 pages with 33(!) line drawings and 6 color photos (albeit all of the nominate subspecies), whereas *Acanthodactylus longipes,* for instance, is accorded just one page, two drawings, and no photograph. Bons and Geniez generally devote only about one half text page (ranging from one quarter of a page to two half pages, in each of the three languages, French, Spanish, and English) to each species.

Despite providing more material, however, Schleich et al. display a great deal of information in an apparently unselective and confusing way. For instance, a two-page color plate is devoted to the different color phases a chameleon can attain. As there is only one species of *Chamaeleo* in North West Africa, this illustration appears unnecessary. It would have been much better to show a specimen of the desert form, C. *chamaeleon "saharicus,"* which has lost the ability of color change to a great extent. This special ecotype (or subspecies?) is not even mentioned. There are many other examples of interesting but superfluous information, such as (still in *C. chamaeleon*) drawings of hemipenis, movements of chromatophores, and the mechanism of tongue protrusion. A few examples from other species include: a sonogram of the distress call of the lacertid *Psammodromus algirus*, flow diagrams of social behavior in *Scincus scincus* and *Uromastyx acanthinura*, a cross section through the head of *Trogonophis wiegmanni*, illustrations of snake movement types, etc. The book could well be intended as an introduction to general herpetology for North African biology students, had it been written in French, the teaching language of most North African universities.

Much of the information presented by Schleich et al. seems to have been extracted from the literature without critical evaluation. There are many inaccuracies, but their sources are difficult to trace, as references to the origin of data and figures are only exceptionally given in an easily traceable way. Despite an extensive bibliography, many relevant articles were missed. I found the following more serious mistakes:

- Plate 51, intended to show *Tarentola boehmei*, in fact shows *T. mauritanica juliae*.
- *Psammophis sibilans* is reported as an inhabitant of Morocco, Algeria and Tunisia. In fact, the only place in North Africa where it occurs is the Nile valley (Brandstätter 1996).
- *Gymnodactylus moerens* is regarded a synonym of *Quedenfeldtia trachyblepharus*. Obviously, the authors overlooked that Arnold (1990) had separated *Q. moerens* as a separate species.
- *Scelarcis perspicillata* is included in *Podarcis*, although it had been demonstrated long ago that it is not related to that genus (Odierna et al. 1987; Mateo and Cano 1991). Other examples of taxonomic differences between the two books are given in Table 1.
- The Egyptian spitting cobra is called *Naja nigricollis*, although the species found in Egypt is in fact *N. pallida* (Golay et al. 1993).
- *Echis coloratus*, the second species of saw-scaled viper in Egypt (Joger 1984), is not included in the Egyptian species list nor in the key.
- *Testudo graeca* which does not inhabit Egypt (Buskirk 1996) appears in the Egyptian key.
- The revision of the *Chalcides chalcides* complex by Caputo (1993) unfortunately came to the attention of the authors once printing had already started. They included the revised taxonomy as an appendix, proposing corrections to the appropriate chapter. However, no corrections were proposed for the species lists (p. 8–9, p. 27, p. 36–51, p. 55–59) where *Chalcides mertensi, C. minutus,* and *C. pseudostriatus* are lacking, and *C. parallelus* appears under the name *C. ghiarai*.

There are some other omissions in those species lists such as *Lacerta pater* (lacking in the general species list, p. 9), *Bufo brongersmai* (not listed in the list of endemics of the Atlantic coastal strip, p. 27), the genera *Scincopus* and *Echis* (lacking in the regional checklist for Morocco, p. 55–56), genus *Agama* (not indicated for Libya, p. 55). In the checklist on p. 55, only one species of *Sphenops* is mentioned for Libya, whereas according to the map on p. 367, three species of that genus should occur there.

Despite a confusing number of species lists concerned with ecological and geographical variables, there is no species checklist for individual countries except a partial one for Egypt (excluding species only known from Sinai and species also occuring in other North African countries) which is presented as an appendix. Trying to extract reliable distribution information from the maps, which are often just raw sketches may result in erroneous or incomplete data. Examples include:

TABLE 1. Differences in the taxonomic treatment of North African amphibian and reptile species (* = more "progressive" taxonomy).

Schleich et al. (1996)	Bons and Geniez (1996)
*Salamandra algira**	*S. salamandra algira*
*Agama impalearis**	*A. bibronii*
Chalcides ghiarai	*Ch. parallelus**
Eumeces (schneideri) meridionalis	*E. algeriensis meridionalis**
Scincus scincus laterimaculatus	*S. albifasciatus laterimaculatus**
*Mesalina simoni**	*M. olivieri simoni*
Podarcis perspicillata	*Scelarcis perspicillata**
Acanthodactylus erythrurus lineomaculatus	*A. lineomaculatus**
Telescopus obtusus	*T. dhara**
*Echis arenicola**	*E. leucogaster*

- *Salamandra algira*: not shown from Tunisia from where it is known (Salvador 1996).
- *Stenodactylus sthenodactylus*: not shown from the Tunisian coast where it occurs (e.g., on the island of Djerba, which is mentioned in the 'island checklist' on p. 53).
- *Trapelus tournevillei*: only a small part of its actual distribution in Tunisia shown.
- *Acanthodactylus longipes*: not mentioned for Tunisia where it is abundant in dune areas.
- *Acanthodactylus scutellatus*: said to occur in Morocco where, according to Bons and Geniez, it is not present.
- *Sphenops delislei*: not mentioned for Morocco/West Sahara.
- *Bufo mauritanicus, Bufo viridis,* and *Mauremys leprosa* are reported to occur south of the Sahara (Mali/Niger). These records are erroneous (Joger and Lambert 1996).

In some difficult species complexes, the authors add to the existing nomenclatural confusion by using different names in different sections of their book. For instance, *Scincus albifasciatus* is listed as a valid species on p. 9, but is included in the species account of *Scincus scincus* and is lacking in the scincid key (p. 322). *Uromastyx* (*acanthinura*) *geyri,* the taxonomy of which is unsettled, appears as full species on p. 8 and 58. *Macrovipera* is sometimes included in *Vipera*. *Dicroglossus occipitalis* is called *Rana occipitalis* in the general section. *Acanthodactylus longipes* and *A. dumerilii* are regarded as semispecies in the *A. scutellatus* complex, whereas in the general section they are not separated from *A. scutellatus*, except in the species list on p. 9. A similar confusion applies to *A. bedriagai*, *A. busacki,* and *A. maculatus* in the *A. pardalis* species group.

TABLE 2. Mapped dots for rare species of Moroccan reptiles.

	Schleich et al. (1996)	Bons and Geniez (1996)
Dasypeltis scabra	2	5
Natrix natrix	7	16
Lamprophis fuliginosus	5	7
Bitis arietans	7	29
Vipera monticola	2	32
Lacerta andreanskyi	6	22
Psammodromus microdactylus	8	14
Mesalina pasteuri	1	6

These deficiencies not only demonstrate an insufficient literature survey but also suggest a lack of field experience.

Jacques Bons and Philippe Geniez, on the other hand, are well known specialists on Moroccan herps as evidenced by their extensive publication lists. Jacques Bons' field data have been accumulated over more than 40 years. Moreover, these authors relied on information gathered from about 200 field observers, among them many prominent herpetologists. The resulting distribution maps are really fascinating. There are two maps for each species: One for the traditional territory of Morocco, depicting single localities, and one for Morocco and the Western Sahara, showing distribution in squares of 22 x 25 km. Schleich et al. have only few dot maps for less common species; a comparison of some of them shows large differences (Table 2).

In contrast to Schleich et al., Bons and Geniez restrict the species part of their atlas to taxonomic and geographic information. Unfortunately, their texts are too short and lack identification characters (except in some cases, as in distinguishing between the two *Quedenfeldtia* species). When they discuss subspecies, as in *Scelarcis perspicillata* and *Tropiocolotes tripolitanus*, or high intraspecific variability, as in *Rana saharica*, they show additional photos. The general part of the text makes up some 50 pages (in fact only half pages, as it is bilingual, French and Spanish, with a rather poor English translation appended). An introduction is followed by a taxonomic list with scientific and vernacular names in three languages (but not in Arabic!). Climate and vegetation are briefly outlined. A biogeographical section classifies all species according to their affinities and gives information on centers of endemism and on altitudinal distribution. The history of herpetological research in Morocco, and the methodology of mapping the 'atlas' are explained. An interesting table displays abundance statistics derived from the number of individual recordings (*Agama bibronii* heading the list with more than 1000 observations; the rarest species being *Echis leucogaster* and *Scincopus fasciatus*). A section on conservation is included.

In conclusion, which book can be recommended for information on the North African herpetofauna? The choice is not easy. Certainly, the work of Schleich et al. contains much more information on the subject than any other. It would be an injustice to the authors not to acknowledge the great effort they have made. However, as outlined above, their uncritical and incomplete treatment of primary literature precludes the use of their work as a handbook and it is too expensive and inadequately illustrated to serve as a fieldguide. It could best be seen as a preliminary draft of a future handbook on North African herpetofauna. As a

source of taxonomic or distribution information, it can only be used with considerable caution. For that purpose, the atlas of Bons and Geniez is much more reliable. However, the latter is restricted to Morocco and the western Sahara.

To the participants of my annual student excursions to North Africa, I am recommending a combination of the taxonomically outdated Saharan fieldguide of LeBerre (1989) with the up-to-date atlas of Bons and Geniez (1996). Together they contain all North African herp species and cost less than the book of Schleich et al. Coming back to my introductory remarks on Böhme's statement, I have to admit that, in a strict sense, his complaint still holds true: a comprehensive and accurate fieldguide on North African herps is still needed.

RODOLFO RUIBAL

Department of Biology, University of California
Riverside, California 92521, USA

For the past fifty years the herpetofauna of Argentina has been José Miguel Cei's subject of study. His first publication on the biology of Argentine amphibians was in 1948 when he was professor at the Universidad Nacional de Tucumán in northern Argentina. Later, as Director of the Instituto de Biologia at the Universidad Nacional de Cuyo in Mendoza, he continued his intensive study of amphibians and published on a diversity of topics ranging from reproductive cycles, ecology, and taxonomy to a series of papers with V. Erspamer on the biochemistry of anuran skin secretions. In 1962 he published *Batracios de Chile* and in 1980 produced *The Amphibians of Argentina*, a 600-page comprehensive study in English published by the Monitore zoologico italiano (Italian Journal of Zoology). This book set a high standard, with detailed descriptions as well as extensive illustrations, including color figures of almost all the species, and extensive ecological information. In the early 1970's he had started studying Argentine reptiles and in 1986 authored, in Spanish, a 500-page book on the reptiles of western and southern Argentina (*Reptiles del Centro, Centro-oeste y Sur de la Argentina*) published by the Museo Regionale di Scienze Naturali in Turin, Italy. The text was a detailed description of each species, complete with ecological information and excellent color photographs of living specimens. The text included an English version of the keys.

Cei's most recent book covers the reptiles of the northern and eastern part of Argentina: *Reptiles del Noroeste, Nordeste y Este de la Argentina*, published in 1993 by the same museum in Turin. This is a 950-page tome presenting the rich and diverse fauna of this mostly tropical and subtropical region. The reptilian fauna of this part of Argentina contains 77 genera, in contrast to the 37 genera found in the more southern portion of Argentina covered in the 1986 volume. Like his previous books, it is profusely illustrated with excellent color photos of live specimens and of the habitats. The keys are in Spanish and English. The geography of the area covered includes a diversity of ecosystems ranging from tropical forests, semi-arid Chacoan habitats, pampas, and Andean mountains and plateaus.

Cei has done extensive field work throughout Argentina and has observed most of the species of this region in nature. This has certainly contributed to the excellent and diverse content of his species descriptions. Cei's taxonomic presentations are detailed and complete. Each species is presented with a diagnosis and if appropriate a discussion of the history of the species. This is followed by a more detailed description, the distribution and finally a section on the biological aspects of the species, including (when available) information about habitat, ecology, reproduction, feeding behavior, etc. The genera are also presented with a historical review and followed by a discussion of generic characters. The section (about 60 pages) on *Liolaemus* presents an excellent summary of the characteristics of the various subgenera and "groups" of this diverse genus. Cei also uses subgeneric classification in *Stenocercus*. He uses "group" classification for numerous genera. He supports his subgeneric and group classification on the arguments of Dubois (1982). Unfortunately, this citation was left out of the bibliography.

The text of this volume is encyclopedic. In his Introduction, Cei includes a section on hemipenal structure, another on karyotypic data, and a further section on biogeography. Under his infraorder Serpentes he presents a detailed discussion of the phyletic relationships of snakes. He follows McDowell's snake classification and presents a sophisticated and interesting discussion of snake evolution. His bibliography is extensive, with the earliest paper cited being a 1770's article by a Jesuit who published on the reptiles and amphibians of Paraguay.

Unfortunately, final proof reading was not possible by Cei and consequently the tome comes with a list of errata and corrections. Most of the errors are minor typos.

The book includes an appendix that adds the results of the Second Argentine Herpetological Congress of 1992 which appeared when the manuscript was at the printers, as well as a number of other papers that appeared at this time.

In summary, this opus is an excellent addition to the more than 40 years of research and publication carried out by Cei. His monographic studies of amphibians and reptiles have set a very high standard for fellow herpetologists.

This two volume set represents an ambitious, and overall successful, attempt to distill all that is known about lizards into bite-sized morsels that are relevant to the hobbyist and amateur herpetologist. Information presented by the author should prove useful to the lizard keeper, but may be of limited use to scientific ventures beyond those reached via animal husbandry. These books originally were written and published in German in 1992. The version reviewed here was translated into English by John Hackworth.

The text is divided into three main divisions; the Introduction (2 pages), The Care and Husbandry of Lizards in the Vivarium (11 pages), and taxon accounts (565 pages). The books also include bibliographies of 323 (Vol. 1), and 338 (Vol. 2) citations that relate chiefly to captive management, and an index.

The Introduction includes background information on reptile classification, and very basic anatomy and life history of lizards and lizard-like reptiles (the author includes crocodilians and *Sphenodon*). This section is informative, but rather short. Most of this information would have been better presented in a separate section on lizard biology, rather than crammed into a two-page introduction lacking figures.

The section on care and husbandry provides a broad overview of vivarium design, lighting, temperature, nutrition, and reproduction. Oddly, this section also provides a chart of lizard squamation and some of the basic gekkonid toe morphologies. This material would have been better suited to a section on basic anatomy.

The taxon accounts are organized by family and subfamily using, in some cases, antiquated and, in other cases, fictional nomenclature. A brief overview is provided for each family, including an estimated number of species recognized, habitats utilized, and some basic defining characters that are attributable to the entire family, a daunting task especially when using paraphyletic groupings. Each family and subfamily is then represented in the text by species that at least occasionally enter the pet trade in Europe or North America. Many species are also depicted in attractive color photos. For each genus the number of species and a general physical description are provided. Species accounts within each genus are arranged alphabetically and organized into sections entitled "Distribution," "Description," "Habitat," and "Lifestyle, husbandry and reproduction." The last of these is generally the longest section.

Throughout the text subtle errors in taxonomy are made. These volumes could have referenced some of the more widely read and accepted systematics papers of recent years. Yet, virtually none of the changes in taxonomy that are associated with phylogenetic analyses of the past decade have been cited. This is most evident in the section entitled "Iguanas: Family Iguanidae," in which one can read about *Anolis* and *Basiliscus*. Frost and Etheridge (1989) elevated the subfamilies within the classic "Iguanidae" to familial status, an analysis and treatment that has been often discussed and debated, but generally accepted (but see Macey et al. 1997).

Additionally, all anoles are treated as *Anolis* of the subfamily "Anolinae." A few species listed as *Anolis* have the current generic name in parentheses (*Anolis* (*Norops*) *allogus*, etc.). In one case, the current genus name is provided in parentheses in the caption to a photo, but not in the text for that species—*Anolis* (*Norops*) *chrysolepis*. Guyer and Savage (1986) formally proposed the resurrection of the genus name "*Norops*" for anoles exhibiting "beta" caudal vertebrae as described by Etheridge (1959). Further reclassification of the genus *Anolis* was detailed by Savage and Guyer (1989) who employed the use of *Norops*, *Ctenonotus*, *Semiurus*, and *Dactyloa* as generic rankings. Although the acceptance of this classification is, at best, spotty, Rogner does list Guyer and Savage (1986) and Savage and Guyer (1989) in the bibliography for Volume 1 (with multiple typographical errors in the latter, including the wrong first initial for Guyer) but does not explain in the text why he chose not to use the nomenclature proposed by these authors.

High quality color photographs are used throughout both volumes. Many are of species seldom encountered by the average U.S. hobbyist. Among these are many species from Australia, Fiji, and Sri Lanka. At least one photo appears to be incorrectly captioned. The photo of a gecko on page 105 of Volume 1 is captioned "*Tarentola delalandii*." However, based on the figure on page 10 of the same volume, it seems that the species is a *Hemidactylus*.

The main goal of this set seems to be to provide information useful in the care and management of captive lizards. Perhaps specialists in the captive care of specific groups of lizards can find minor fault with some sections. For example, basic care information for all geckos of the genus *Phelsuma* is provided in the section for *P. abbotti* (alphabetically the first species treated) and all other species are referenced back to *P. abbotti*. Care and management information for all other species begins with the "See *P. abbotti*" or cites some other species that is, in turn, referenced to *P. abbotti*. Some species contain augmented information, indicating that the care requirements within the genus are not absolutely uniform. However, for most species the qualifying sentences are not strong enough, nor do they possess enough information to ensure that the reader will not become confused and maintain the species as one would *P. abbotti*. Few, if any, day gecko breeders consider *P. abbotti* to be representative of the genus in terms of its needs in captivity. In fact, it could be argued that there is no single representative "typical" species of *Phelsuma* with respect to care. A more valuable reference for care and maintenance of day geckos might be McKeown's (1993) book on the subject.

The last three chapters of Volume 2 are devoted to Amphisbaenia, Rhynchocephalia, and Crocodilia. It is somewhat disappointing that a book that could offer so much information for the lizard-keeping enthusiast apparently needs to include these non-lizard groups. Rogner explains that amphisbaenians may not,

in fact, be lizards and cites Böhme (1988) as evidence. However, Rogner does not then explain why he includes these animals in his book. That is, he provides evidence against their inclusion, but includes them anyway. The information on husbandry of amphisbaenians is limited to four species, but is particularly interesting given their rarity in the pet trade.

Tuataras, another group of non-lizards, are referred to as the "Bridged Lizards" (the literal translation of the German "Brückenechsen"). Rogner provides no indication that they are not lizards, aside from noting that they belong to the Order Rhynchocephalia. He also indicates a single species of the Order, *Sphenodon punctatus*, but refers to three subspecies including *S. p. reischeki* "which some herpetologists consider to be a separate species." In fact, the second species is *Sphenodon guentheri*. Rogner continues by providing information on the care in captivity for some of the tuataras kept in zoos. While this information is interesting it is not practical for the keeper, given the complete protection afforded tuataras.

Crocodilians are described in the text as "Armoured Lizards." Rogner points out, correctly, that they are "more closely related to birds than to any other reptiles living today," but does not indicate why he includes them in his treatise on lizards. Inclusion of these three groups of reptiles (Amphisbaenia, Rhynchocephalia, and Crocodilia) in a book on lizards may be similar to including lungfish in a book on frogs, or platypus in a book devoted to waterfowl. While the information is interesting and of some use, and the photos are attractive, it simply doesn't fit with the theme of the book. If the title of the two volume set were "Lizard-shaped Reptiles" then they could logically be included, but it is not.

Taxonomic errors and the inclusion of non-lizards aside, Rogner's two volume set "Lizards" is the most thorough and up-to-date popular treatise of the general biology and care in captivity of non-ophidian squamates to come along in quite some time. Its value as a reference for the general husbandry of many species may be unprecedented as some species are covered nowhere else in the hobbyist literature. No other current reference on this topic covers as much of the diversity of lizards in as much detail as this set. This set should make a welcome addition to most lizard keepers' libraries, providing that it is not relied upon as a taxonomic reference.

PUBLICATIONS RECEIVED

Frogs and Reptiles of the Sydney Region, by Ken Griffiths. 1997. University of New South Wales Press, Sydney, Australia. 125 pp. Softcover. US $24.95. ISBN 0 86840 432 2. [Available in the USA from International Specialized Book Services, Inc., 5804 N.E. Hassalo Street, Portland, Oregon 97213-3644, USA].

A short guide to the 35 frogs and 70 reptiles found in greater Sydney and adjacent areas of New South Wales. Species accounts include identifying features, brief ecological notes, species status in the Sydney region, and one or more color photos per species. In addition, short sections on observing, recording, and photographing amphibians and reptiles, reptile legislation, a glossary, selected secondary references, and an index are provided. The reptile section of the book is an updated and revised version (with new photographs) of the author's 1987 book *Reptiles of the Sydney Region* (Three Sisters Productions, Winmalee, NSW).

Herpetología Neotropical, Actas del II Congresso Latinoamericano de Herpetología, II Volumen, edited by Jaime E. Péfaur. 1996. Universidad de Los Andes, Mérida, Venezuela. 451 pp. Softcover. US $40.00. ISBN 980-221-944-4. [Available from the editor, Facultad de Ciencias, Núcleo La Hechicera, Universidad de Los Andes, Mérida 5101, Venezuela].

This is the second volume published as a result of the Second Latin American Herpetolgical Congress held in Mérida, Venezuela in 1990 (the first being the *Directotio de Herpetologos Neotropicales*, 1994). Included are 25 contributions dealing with the anatomy, evolution, reproduction, ecology, biogeography, and management of the Latin American herpetofauna, along with the herpetological history, and bibliography of Venezuela. Each paper is written in Spanish, Portuguese, or English. Although other regions are represented, Venezuelan and Brazilian contributions are the most numerous. All scientific contributions are fully referenced and most are accompanied by black and white photographs, illustrations, maps, or graphs.

Biologie und ôkologie der Kreuzkrîte, by Ulrich Sinsch. 1998. Laurenti Verlag, Dr. Burkhard Thiesmeier, Akademiestr. 39, D-44789, Bochum, Germany. 222 pp. Softcover. DM 44 (approx. US $25 + $3 postage). ISBN 3-933066-01-8.

This monograph provides a comprehensive overview of the biology of the natterjack toad (*Bufo calamita*), a well-known European species of particular conservation concern in some areas. Included are sections on evolution and taxonomy, biogeography, physiology, behavior, ecology (reproductive, larval, adult, and population), and conservation. The work pulls together the author's own extensive research on this species as well as that conducted by others throughout Europe. It includes an extensive bibliography (through 1997) and a subject index. Over 100 black and white illustrations and photos and four color plates complement the text. The book should be of special value to amphibian biologists with ecological and conservation interests and to anyone working with the European herpetofauna.

Information for Contributors

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes of a semi-technical or non-technical nature, as well as book reviews, institutional features, commentaries, regional and international herpetological society news, research requests of SSAR members, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (see inside front cover for Editor's address).

Authors should submit an original and two copies of manuscripts. Manuscripts should be typewritten, double-spaced, on 21.5 x 28 cm (8.5 x 11 inch) white paper. Refer to this issue of ***HR*** for style and format information. Detailed information for submissions to Geographic Distribution, Natural History Notes, and Recent Population Changes appear in a recent issue of ***HR*** under their respective headings. **Corresponding authors should include an e-mail address (if available); this will greatly facilitate communication with the editors.**

Originals of illustrative material (e.g., tables, photographs, or diagrams) should be submitted with the text, with appropriate precautions taken to ensure delivery without damage. Illustrations should be discussed in the text and numbered sequentially with Arabic numbers. References to illustrations should be placed in parentheses at the end of sentences. Original photographs should be submitted as black and white glossy prints. For further guidelines, authors should consult *Scientific Style and Format: The CBE Manual for Authors, Editors, and Publishers* (6th edition, 1994, Council of Biology Editors, Inc., 11 South LaSalle Street, Suite 1400, Chicago, Illinois 60603, USA).

Submissions for Natural History Notes, Geographic Distribution, Herpetological Husbandry, Current Research, Regional Society News, and Legislation & Conservation should be sent directly to the appropriate section editor. Please send review copies of books to the Book Review Section Editor. Manuscripts intended for publication as Articles, Points of View, Techniques, or Recent Population Changes, as well as news notes and other material, should be sent to the Editor. Deadline for receipt of meeting announcements, news notes and related material is two months prior to each issue (e.g., 1 January for March issue).

The receipt of a manuscript by an editor will be promptly acknowledged. Although the advice and assistance of external reviewers will be sought for all manuscripts, the Editor has final responsibility for deciding whether a manuscript is suitable for publication. Notes submitted for publication in Geographic Distribution and Natural History Notes ordinarily will be reviewed by the Section Editors only. The editors reserve the right to edit a manuscript, but substantial alterations will not be made without permission of the primary author.

Reprints

Reprints of notes or articles published in ***HR*** should be ordered using the forms provided to authors as the issue goes to press. Proofs are not sent to authors of Geographic Distribution notes; these authors should indicate (at time of submission) whether reprints are desired and if so, the appropriate order forms will be sent prior to publication. These are also available upon request from the editor or managing editor.

Advertising

Herpetological Review accepts commercial advertising. Rates and copy information are available from Elizabeth A. Johnson, *HR* Advertising Manager, 35 Eighth Street, Frenchtown, New Jersey 08825, USA (tel. 908-996-4056 EST; e-mail: ejohnson@ptdprolog.net).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA. Periodical postage rates are paid at St. Louis, Missouri with additional entry offices. **POSTMASTER:** Send address changes to *Herpetological Review*, Department of Biology, St. Louis University, 3507 Laclede Avenue, St. Louis, Missouri 63103-2010, USA. All rights reserved. No part of this periodical may be reproduced without written permission of the editor. Please notify Robert D. Aldridge, SSAR Treasurer (address and contact numbers on inside front cover) regarding missing or damaged issues, as well as for changes of address.

Catalogue of American Amphibians and Reptiles

The ***Catalogue*** consists of loose-leaf accounts of taxa prepared by specialists, including synonymy, definition, description, distribution map, and comprehensive list of literature for each taxon. Covers amphibians and reptiles of the entire Western Hemisphere. Available by subscription only. See inside front cover to start annual subscription. Use the prices below to order back issues.

COMPLETE SET: NUMBERS 1 – 640		$340
INDEX TO ACCOUNTS 1 – 400: Cross-referenced, 64 pages		$5
INDEX TO ACCOUNTS 401 – 600: Cross-referenced, 32 pages		$5
SYSTEMATIC TABS (Ten tabs to fit binder: "Class Amphibia," "Order Caudata," etc.)		$6
IMPRINTED POST BINDER (Note: one binder holds about 200 accounts)		$35
INCOMPLETE SET: NUMBERS	1 – 190	$75
	191 – 410	$85
	411 – 640	$190

To order: make checks payable to "SSAR" and mail to Robert D. Aldridge, Department of Biology, St. Louis University, St. Louis, Missouri 63103-2010, USA (fax 314-977-3658). e-mail: ssar@sluvca.slu.edu.

Herpetological Review

Volume 29, Number 2 June 1998

POINTS OF VIEW

Bibliographic Accuracy: Importance in Herpetological Publications ..... by E. A. Liner and V. H. Hutchison 71

ARTICLES

Arrangement of Oviductal Eggs and Intra-clutch Egg Shape Modification in the Habu *Trimeresurus flavoviridis* (Viperidae) ..... by M. Nishimura 76

Variation, Distribution, and Taxonomic Status of the Xantusiid Lizard *Lepidophyma tarascae* ..... by U. Guzman-Villa, O. Flores-Villela, W. Schmidt-Ballardo, and R. L. Bezy 78

The Circular Aesculepian Temple (Tholos) at Epidauros, Greece: An Early Snake Pit?..... by B. H. Brattstrom 79

Reticulate Melanism in Southwestern Populations of *Chrysemys picta bellii* (Testudines: Emydidae) ..... by J. N. Stuart 80

Mummification Following Winterkill of Adult Green Frogs (Ranidae: *Rana clamitans*) ..... by M. J. Lannoo, J. A. Holman, G. S. Casper, and E. Johnson 82

A Glimpse into the Life of a Zoo Herpetologist ..... by J. B. Murphy and W. Card 85

Range Extensions of Some Anuran Species for Santa Catarina and Rio Grande do Sul States, Brazil ..... by P. Christiano de Anchietta Garcia and G. Vinciprova 117

Herpetofauna of the Highly-polluted Onondaga Lake Ecosystem, Onondaga County, New York ..... by P. K. Ducey, W. Newman, K. D. Cameron, and M. Messere 118

TECHNIQUES

A Portable Device for Restraining Frogs ..... by M. T. Christy 90

A New Method for Marking Individual Anuran Larvae ..... by T. M. Rice, S. E. Walker, B. J. Blackstone, and D. H. Taylor 92

Sticky Traps: An Effective Way to Capture Small Terrestrial Lizards ..... by S. Downes and P. Borges 94

Comparison of Histological Staining Procedures for Skeletochronological Studies ..... by C. R. Rossell, Jr. and J. L. Sheehan 95

BOOK REVIEWS

Snakes: The Evolution of Mystery in Nature ..... reviewed by R. A. Seigel and N. A. Seigel 120

Herpetology ..... reviewed by A. M. Bauer 121

Amphibians and Reptiles of North Africa
Amphibiens et Reptiles du Maroc (Sahara Occidental compris), Atlas biogéographique ..... reviewed by U. Joger 123

Reptiles del Noroeste, Nordeste y Este de la Argentina: Herpetofauna de las Selvas Subtropicales, Puna y Pampas ..... reviewed by R. Ruibal 126

Lizards ..... reviewed by G. J. Watkins-Colwell 127

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

WWW: http://falcon.cc.ukans.edu/~gpisani/SSAR.html

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

ANNUAL DUES AND SUBSCRIPTIONS: Annual membership dues for the year 1998 in the Society for the Study of Amphibians and Reptiles are as follows: Individual membership US$40; Student membership $30; Family membership $55. $16 of the amount of a membership pays for a subscription to *Herpetological Review* for one year. $21 of the amount of a membership pays for a subscription to *Journal of Herpetology* for one year. Remaining funds help support Society activities. Additional fee for air mail postage outside USA $35 for one year. Institutional subscriptions for *Herpetological Review* are $70 and individual subscriptions may be purchased for $24. All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its news-journal, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*. Subscription to the *Catalogue of American Amphibians and Reptiles*: Individuals $20; Institutions $20.

Payment must be made in USA funds, payable to "SSAR," or by International Money Order, or with VISA or MasterCard (account number and expiration date must be provided). Payment should be sent to: Robert D. Aldridge, SSAR Treasurer, Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA. Fax: (314) 977-3658; e-mail: ssar@sluvca.slu.edu.

Future Annual Meetings

1998 — University of Guelph, Guelph, Ontario, Canada, 16–22 July (James P. Bogart, Chair).
1999 — University of Pennsylvania, University Park, Pennsylvania, USA, 24–30 June (Jay Stauffer, Chair).

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES
1998 ANNUAL MEETING
together with
AMERICAN SOCIETY OF ICHTHYOLOGISTS AND HERPETOLOGISTS
THE HERPETOLOGISTS' LEAGUE
CANADIAN ASSOCIATION OF HERPETOLOGISTS
16 – 22 July 1998
University of Guelph, Ontario, Canada

Keynote Address: "THE EVOLUTION OF MORPHOLOGICAL NOVELTIES," by Sharon Emerson, The Herpetologists' League Distinguished Herpetologist (University of Utah).

Symposium: "RECENT ADVANCES IN ANURAN COMMUNICATION: A SYMPOSIUM HONORING DR. STAN RAND." *Organizer:* Michael J. Ryan, Clark Hubbs Regents Professor in Zoology, Department of Zoology, University of Texas, Austin Texas 78712, USA; e-mail: mryan@mail.utexas.edu. Tel: (512) 471-5078; Fax: (512) 471-9651.

Symposium: "PHENOLOGY OF FISHES, AMPHIBIANS, AND REPTILES: INTEGRATING ORGANISM-LEVEL AND POPULATION-LEVEL PERSPECTIVES." *Organizers*: Eric Schultz and Kentwood Wells, Department of Ecology and Evolutionary Biology, University of Connecticut, Storrs, Connecticut 06269-3042, USA.

Symposium: "TO FREEZE OR NOT TO FREEZE: AMPHIBIANS AND REPTILES IN THE COLD." *Organizer:* Kenneth B. Storey, Department of Biology, Carleton University, 1125 Colonel By Drive, Ottawa, Ontario, Canada K1S 5B6; e-mail: kbstorey@ccs.carleton.ca. Tel: (613) 520-3678; Fax: (613) 520-4497.

Symposium: "HERPETOLOGY IN THE LAB AND FIELD: A SYMPOSIUM IN RECOGNITION OF THE CAREER OF RONALD A. BRANDON." *Organizers:* Steve Reilly, Department of Biological Sciences, Ohio University, Athens, Ohio 45701, USA; e-mail: reilly@ohio.edu. Tel: (614) 593-3343, and Ronn Altig, Drawer GY, Department of Biological Sciences, Mississippi State University, Mississippi State, Mississippi 39762, USA. e-mail: rga2@Ra.MsState.edu. Tel. (601) 325-7561.

Conservation Forum/Point-Counterpoint: "CITES: BENEFIT OR HINDRANCE TO THE CONSERVATION OF AMPHIBIANS AND REPTILES." *Participants:* Sue Lieberman (U.S. Fish and Wildlife Service), Brian Bowen (University of Florida). *Organizer:* C. Kenneth Dodd, Jr., Florida Caribbean Science Center, U.S. Geological Survey, 7920 N.W. 71st Street, Gainesville, Florida 32653, USA. e-mail: Ken_Dodd@usgs.gov.

Contributed Paper and Poster Presentations: Several concurrent sessions will be held each day throughout the conference.

Student Paper Awards: Seibert Prizes (US $200 each) will be awarded in four categories: Systematics, Ecology/Evolution, Conservation, and Physiology/Morphology. Refer to the December 1997 issue of *HR* for details.

Student Travel Grants: Ten travel grants of US $200 each will be available for SSAR student members. Refer to the December 1997 issue of *HR* for details.

Multimedia Presentations: "HERPETOLOGY OF THE WEST" and "AMPHIBIANS OF THE APPALACHIANS" by David Dennis and Eric Juterbock; "HERPETOLOGICAL NAMESAKES" by Kraig Adler and David Dennis.

Social Activities: General Reception at the University Center Building, SSAR Auction, Picnic at Guelph Lake, ROMMY II, Graduate Student Reception, and ASIH Banquet.

Field Trips: Metro Toronto Zoo, Long Point Provincial park, Royal Ontario Museum, Niagara Falls and Winery.

Live Exhibit: Live amphibians and reptiles of Ontario will be on display and available for viewing and photo sessions.

Vendors: Books, carvings, jewelry, T-shirts, and equipment of interest to herpetologists.

Costs: Pre-registration $170.00 Canadian (approx. US $120) regular, $85.00 CAN (approx. US $60) student/accompanying person. After April 1, 1998, costs are $220.00 CAN (approx. US $155) regular, $125.00 CAN (approx. US $88) student/accompanying person.

Further Details: See December 1997 issue of *HR* (pp. 169–171). Meeting Announcement and Call for Papers was mailed to all Canadian, U.S., and Mexican members of SSAR in January 1998. Overseas members wishing to receive this information may do so by contacting *Tana McDaniel, Department of Zoology, University of Guelph, Guelph, Ontario, Canada N1G 2W1. Tel: (519) 824-4120 ext. 6260; fax: (519) 767-1656; e-mail: meeting@uoguelph.ca.* Please visit the meeting web site at http://www.uoguelph.ca/~ichsherp for additional and updated information.

SSAR BUSINESS

New Conservation Brochure Available

The SSAR Conservation Committee has produced a black and white brochure entitled "Conserving Amphibians and Reptiles." The brochure is posted on SSAR's Conservation page at http://falcon.cc.ukans.edu/~gpisani/conservation.html. Individuals or organizations desiring hard copies can download the brochure using free Acrobat software, available through the web site. Please use this option as quantities are limited and there are no postage costs to the Society! You may run off as many copies as needed for distribution. Copies of the brochure also can be obtained through the Publications Secretary or by writing: *Dr. Ken Dodd, U.S. Geological Survey, 7920 NW 71st Street, Gainesville, Florida 32653, USA.*

SSAR Grants-in-Herpetology Committee Annual Report (1998)

An award in the amount of $500 was made to each of the following individuals:

Conservation.—**Marc J. Mazerolle**, Dalhousie University. Project title: "Amphibian abundance, movements, and population structure in harvested and pristine ombrotrophic peat bogs of southeastern New Brunswick."

Laboratory Research.—**Kyle G. Ashton**, University of Colorado. Project title: "The evolution of body size within *Crotalus viridis*, the western rattlesnake."

Field Research.—**Sarah Annette Conditt**, University of Missouri. Project title: "Vocal mediation of mating tactic switches in the green treefrog, *Hyla cinerea*." **Stephanie M. Rollmann**, University of Chicago. Project title: "Courtship pheromones, female receptivity, and sexual isolation in plethodontid salamanders."

Travel.—**Rafe M. Brown**, University of Texas. Project title: "Biogeography, systematics and evolution of direct development in platymantine ranids of SE Asia and southwestern Pacific islands."

Education.—**Trevor A. Hare** and **Dennis Caldwell**, Tucson Herpetological Society. Project title: "Tucson Herpetological Society Conservation Publications and Distribution."

1998 Grants-in-Herpetology Committee.—Carole L. Hom, University of California, Davis; Randy Jennings, Western New Mexico University; Julian C. Lee (Chair), University of Miami; Joseph Mendelson III, University of Kansas; Janice Perry, Arizona-Sonora Desert Museum; Barbara Savitzky, Christopher Newport University; Kelly Zamudio, University of California, Berkeley.

SSAR congratulates the 1998 GIH recipients and thanks the committee members for their efforts.

About Our Cover: *Emys orbicularis*

Emys orbicularis, the European Pond Turtle, is unique in being the only Old World member of the subfamily Emydinae. It has now and then been observed throughout Denmark during this century, but such specimens generally have been considered released pets. However, in 1996 four turtles were found in Central Jutland (mainland, western Denmark) in an area rich in forests and freshwater habitats. In the last 20 years about 24 specimens have been observed within a radius of 20 km.

The four new specimens were morphologically similar to the nominate subspecies (rather big, dark colored, and males with a reddish brown iris) indigenous to the northern part of the range. Genetic tests, however, showed that three of the specimens possessed the same DNA haplotype as populations from Poland, Lithuania, and the Black Sea, that is, the eastern part of the species' range. The fourth specimen was of a hitherto unknown haplotype, but definitely descendent from the type distributed in East Germany and Hungary (Bringsøe 1997. Forekomst af europæisk sumpskildpadde, *Emys orbicularis*, i Danmark. Nord. Herpet. Foren. 40[2]:57–64). These haplotypes have been termed Ia and IId respectively (Lenk et al. 1998. Phylogeographic patterns in the mitochondrial cytochrome b gene of the European pond turtle [*Emys orbicularis*]: First results. Mertensiella: in press).

Although traps were set up and searching was intensified during 1997, only two more specimens were found in the possible metapopulation of Central Jutland. DNA analyses indicated an eastern origin (haplotype Ia). If these specimens had been introduced in this century, they would probably have originated from South Europe, the source of most specimens collected for the pet trade. However, the genetic studies clearly indicate that none of the Jutland specimens originated from South European stock.

It is possible that *E. orbicularis* immigrated to Denmark via two routes: one from the south through Germany, and another from the east over the Baltic as the Baltic Sea was a freshwater lake ca. 9000 years ago. Similar dispersal patterns are believed to apply to other Danish animal species.

One proof for viable populations being able to survive in Denmark is still missing: observation of young. However, juveniles are shy and may be difficult to observe. Hatchlings of *E. orbicularis* often hibernate in the nests, which makes them vulnerable to frost. From northern Germany it is known that they often die under these circumstances.

Thus, it is still an open question whether the Danish occurrences form indigenous populations or have been introduced, or if they are a mixture of both. Certainly, *E. orbicularis* is very rare in Denmark. Otherwise the northernmost known breeding populations are in southern Lithuania, at a latitude slightly south of Central Jutland.

The cover photo was taken by **Henrik Bringsøe** on 13 June 1997 on a field trip during the Sixth Nordic Herpetological Symposium held in Ry, Denmark. The locality of this individual is the lake Velling Igelsø (measuring 380 x 250 m), where most of the specimens from 1996–1997 have been found. It is a male of haplotype Ia which had been caught in the lake shortly before and which was now going to be released.

The photo was taken with ordinary equipment consisting of an old Olympus OM1 body and 28 mm Olympus lens on Kodachrome 200 film, under natural light. In order to take the photo from the same level as the turtle, the camera was held as close to the water surface as possible. A cloud cover prevailed on this day, a common condition in the relatively cold and humid Central Jutland.

Bringsøe describes himself as "an amateur working with a number of disciplines of herpetology, including ecology, conservation, and herpetoculture. Two main areas of my activities are herpetology of Greece and Denmark." He is a contributor to one saurian volume of the German work *Handbuch der Reptilien und Amphibien Europas* and will be an author in the chelonian volume. He currently serves as the chair of Nordisk Herpetologisk Forening—the Scandinavian region's largest herpetological society, and is an NGO advisor to Denmark's CITES authority.

Separation and imaging of Bringsøe's photograph is the work of **Jim Bridges** of Herpeto, Inc., Hollywood, Florida.

NEWSNOTES

New Gecko Society Launched

The Global Gecko Association (GGA) is a new organization dedicated to gecko enthusiasts worldwide. Membership is open to anyone with an interest in gekkonids, from the professional herpetologist to the hobbyist.

The GGA is a not-for-profit organization committed to promote interest in gekkonids in a whole variety of ways, from responsible captive care, to study in the wild, conservation, academic research and beyond. Furthermore, the GGA will serve people who are interested in gekkonids by providing a voice and means of communicating and sharing of resources and ideas.

Members will receive two issues of the Association's Journal annually, together with regular members' Newsletters. The *Journal of the Global Gecko Association* will be produced in color and contain articles and papers, book reviews, interviews and other items of interest that reflect the full breadth of the GGA's objectives. Many of the leading figures in the "gecko world" have agreed to contribute. Newsletters will keep members fully updated with Association events, gecko related news and views from around the world, veterinary advice, and provide a mechanism for members to communicate with each other. Advertising will be accepted for the Newsletters only.

For membership and other information visit the GGA web-site at http://www.gekkota.com or write to: *Global Gecko Association, P.O. Box 739, Westview Station, Binghamton, New York 13905, USA.*

J. Larry Landers Student Research Award

The Gopher Tortoise Council annually awards the J. Larry Landers Student Research Award to the best student research project. Awards have averaged approximately $500 over the past few years. The focus of the project can be on the gopher tortoise, its habitat, or related areas of interest. Applications should include an outline of the project, a proposed budget, and a brief vita. To be considered for the 1998 award, proposals should be received by 31 August 1998. Proposals should be sent to: *Bob Herrington, Chairman of the Research Advisory Committee, Department of Biology, Georgia Southwestern State University, Americus, Georgia 31709, USA.*

Charles Stearns Grant-in-Aid for Herpetological Research at the California Academy of Sciences

The Department of Herpetology is pleased to provide limited financial aid—mostly to cover round trip transportation and limited per diem expenses—to graduate students who wish to visit our collections to support research in systematics.

Proposals should include a short—no more than one page—description of the research project, a budget, and a letter of support from the student's faculty advisor.

Proposals are due on 15 October 1998, with notification by 1 December 1998. Grantees are expected to complete their Academy visit by 15 September 1999. Please call 415-750-7037 for further information.

Send proposals to: *Herpetology Research Grants, Department of Herpetology, California Academy of Sciences, Golden Gate Park, San Francisco, California 94118-4599, USA.*

Ernie Liner to Receive Honorary Doctorate

Long-time SSAR member Ernest A. Liner, of Houma, Louisiana, is to receive an honorary Doctor of Science degree from the University of Colorado, Boulder, at its summer commencement ceremonies on Saturday, 8 August 1998. Ernie, as he is affectionately known to herpetologists throughout North America, is an amateur herpetologist. Until his retirement in 1987, he was employed for most of his professional life by the pharmaceutical firm of E. R. Squibb and Sons.

Since 1949, Ernie has published nearly 100 titles, mostly on the herpetofaunas of Louisiana and Mexico. He published an invaluable checklist of the amphibians and reptiles of Mexico, together with their Spanish and English common names, in 1994. Currently, he is continuing his monographic work on the herpetology of Nuevo Leon and has also assumed responsibility for updating the bibliographic analyses of the Mexican herpetofauna initiated by Hobart and Rozella Smith. He has produced highly useful herpetological indices to numerous journals and is presently completing a monumental index to the entire multivolume series *Biology of the Reptilia*, edited by Carl Gans and now published by SSAR.

Ernie is a member of numerous herpetological societies and has served on the governing boards of both ASIH and SSAR. Besides his herpetological research and activities, Ernie is a grower of prize-winning orchids and a renowned chef. He published A Herpetological Cookbook in 1978, including such recipes as "Fricassee of Iguana," "Congo Eel with Cucumbers," and "Picayune Frogs a la Creole." The book is not without scientifically appropriate instructions, for example, the recipe for "Ophidia a la Minton" begins: "Skin and gut snake. Remove tail with scent glands. Behead and make skull of head. . . ." A new, enlarged edition is being issued this summer by the publisher of Reptile & Amphibian Magazine.

SSAR congratulates Ernie on this high honor.

Wildlife Links: Request for Proposals

The National Fish and Wildlife Foundation, through a cooperative agreement with the United States Golf Association, requests preproposals for research and management projects that address wildlife conservation needs on golf courses. Areas of interest include: examination of management and design options for increasing biodiversity on golf courses; research to determine the role of habitat characteristics in the designation of golf courses as wildlife corridors or barriers; preparation of management guidelines for specific species or species suites; programs to monitor the success of wildlife habitat conservation programs on golf courses; and the effects of golfer and maintenance activities on wildlife. All projects must address issues of management concern to the golf industry, and should provide management recommendations applicable on at least a regional basis. Approximately $80,000 will be available. Request should not exceed $25,000, yet multi-year funding is possible.

Deadline for preproposals is 31 July 1998; full proposal deadline will be early September 1998, with funding available in Feb-

ruary of 1999. For preproposal guidelines, contact: *Katie Distler, NFWF, 1120 Connecticut Ave. NW, Suite 900, Washington, DC 20036, USA; tel. (202) 857-0166; e-mail: distler@nfwf.org.*

Loggerhead Sea Turtle Bibliography Changes WWW Site

The comprehensive bibliography of the loggerhead sea turtle has changed its WWW location. It can now be accessed through the Florida Museum of Natural History's herpetology home page at http://www.flmnh.ufl.edu/natsci/herpetology/herpetology.htm. The site contains references to more than 2000 citations on extant and fossil *Caretta*. In addition, there is now a search feature, new graphics, and full use of specialized grammatical marks in international languages. The references have been updated through November 1997. The bibliography will be updated every 6–12 months. For more information contact: *Dr. Ken Dodd, U.S. Geological Survey, 7920 NW 71st Street, Gainesville, Florida 32653, USA.*

MEETINGS

Meetings Calendar

12–15 June 1998—Highlands Conference on Plethodontid Salamanders, Highlands Biological Station, Highlands, North Carolina, USA. For more information contact: Plethodontid Conference, Highlands Biological Station, P.O. Box 580, Highlands, North Carolina 28741, USA, or send an e-mail message to Judy Hill at: JHILL@wpoff.wcu.edu. Additional information: http://www.wcu.edu/hibio.

25–27 June 1998—22nd Annual Meeting of the International Herpetological Symposium, Inc., Holiday Inn-Cincinnati Airport, Cincinnati, Ohio, USA. Contacts: Stan Draper, IHS Secretary, P.O. Box 16444, Salt Lake City, Utah 84114-0444, USA; e-mail: sdraper@npsp.com; or Pete Strimple, Liaison Committee Chair, 5310 Sultana Drive, Cincinnati, Ohio 45238, USA; tel. (513) 451-2392; e-mail: pds0404@aol.com.

16–22 July 1998—41st Annual Meeting, Society for the Study of Amphibians and Reptiles; 46th Annual Meeting of The Herpetologists' League; 78th Annual Meeting, American Society of Ichthyologists and Herpetologists. Hosted by the University of Guelph, Guelph, Ontario, Canada. *Refer to meeting announcement in this issue for details.*

1–5 September 1998—Third International Asian Herpetological Meeting, Almaty, Kazakhstan. To receive the First Announcement and Preliminary Registration Form, please contact one of the meeting organizers: Dr. Tatjana Dujsebayeva, Department of Biology, Kazakh State University, Al-Farabi Prospect, 71, Almaty, 480078, Kazakhstan; tel. (3272) 472677; fax (3272) 472609; e-mail: zool@plague.almaty.kz; Dr. Natalia Ananjeva, Department of Herpetology, Zoological Institute, Universitatskaja nab., 1, Saint-Petersburg, 199034, Russia; tel. (812) 2180711; fax (812) 2182941; e-mail: anb@zisp.spb.su; or Dr. Theodore Papenfuss, Asiatic Herpetological Research, Museum of Vertebrate Zoology, University of California, Berkeley, California 94720, USA; tel. (510) 642-3567; fax (510) 643-8238; e-mail: asiaherp@uclink2.berkeley.edu.

13–17 May 1999—Fourth International Symposium on Isolated Vertebrate Communities in the Tropics, Bonn, Germany. Hosted by the Zoologisches Forschungsinstitut und Museum Alexander Koenig. To receive announcements and to obtain further information, please contact: Prof. Dr. W. Böhme, Adenauerallee 160, 53113 Bonn, Germany; tel. +49 228 91 22 250, fax ++49 228 216 979, e-mail: r.hutterer.zfmk@uni-bonn.de.

3rd Annual Meeting of the Canadian Amphibian and Reptile Conservation Network

The 3rd Annual Meeting of the Canadian Amphibian and Reptile Conservation Network will be held in conjunction with the 8th Annual Meeting of the IUCN/SSC Task Force on Declining Amphibian Populations in Canada (DAPCAN), at the University of Saskatchewan, Saskatoon, Saskatchewan, Canada, from 1–5 October 1998.

The principal feature of this year's conference will be a symposium on the Conservation Biology and Monitoring of Reptile Populations in Canada, plus our regular program of featured speakers, research papers, posters, workshops, field trips, discussions, and a general meeting on all aspects of the conservation biology of amphibians and reptiles in Canada.

Overnight field trips are planned to Grassland National Park and the South Saskatchewan River Escarpments. Topics that are being considered for symposia or round-table discussion are: Herpetological Education, Ethics, and Highway Mortality.

Please forward your ideas, comments, suggestions or proposals for this meeting to: Andrew Didiuk, Local Organizer; e-mail: Andrew.Didiuk@ec.gc.ca; tel: 306-975-4087; fax: 306-975-4089.

CURRENT RESEARCH

The purpose of **Current Research** is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a wide variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Anne Maglia or Christopher Sheil; postal and e-mail addresses may be found on the inside front cover. Comments and suggestions are also welcome.

The current contents of various herpetological publications can now be found on the World Wide Web. At present, more than 20 publications are listed. The Web site address is:

http://www.sisna.com/users/Herpbooks/Contents.html

Adhesive Tail Tips of Carphodactyline Geckos

Bauer employs electron microscopy to visualize and describe the morphology of the adhesive tail tips of carphodactyline geckos (Reptilia: Diplodactylidae). He surveyed representatives of the genera *Naultinus, Hoplodactylus, Bavayia, Eurydactylodes,*

Rhacodactylus, and *Pseudothecadactylus* and determined that the New Caledonian and Australian species exhibit discrete, adhesive pads similar in gross morphology to the subdigital scansorial pads. The internal structure of these pads closely resembles that of the subdigital scansors as well. These adhesive tail tips show a phylogenetic trend toward increasing complexity. Similarities among the microstructures of the subdigital and tail tip scansorial pads represents phylogenetic convergence and Bauer considers them as iterative homologues of one another.

BAUER, A. M. 1998. Morphology of the adhesive tail tips of carphodactyline geckos (Reptilia: Diplodactylidae). J. Morphol. 235:41–58.

Developmental Temperatures Influence Turtle Temperature Choice and Growth Rate

In this investigation, the author reports on her study of the effects of embryonic temperature on juvenile temperature choice and growth rate in the Snapping Turtle, *Chelydra serpentina,* a species with known temperature-dependent sex determination (TSD), with males produced at intermediate incubation temperatures, and with sexual dimorphism (males larger than females). This study examines the hypothesis that male-producing egg temperatures maximize growth rates and determines and measures the separate effects of embryonic temperature and sex on the growth rate and temperature choices of juveniles. The author found incubation temperature to be linearly and negatively correlated with growth rate of male and female juveniles (i.e., male-producing temperatures enhanced, but did not maximize growth rates). Developmental temperature also was found to be negatively correlated with juvenile temperature choice. Temperature choice was found to be repeatable, even after a six-month hibernation period. The author comments that the multiple effects of embryonic temperature may create long-term differences between the physiology and behavior of male and female *C. serpentina* and may have important implications for the evolution of TSD.

O'STEEN, S. 1998. Embryonic temperature influences juvenile temperature choice and growth rate in snapping turtles *Chelydra serpentina.* J. Exp. Biol. 201:439–449.

Median Lingual Process of Frogs

The authors report the discovery of prominent median protuberances on the tongue of eight species of *Colostethus* (Anura: Dendrobatidae), a surprising find that is the first of its kind among New World anurans. Previously, median protuberances of the tongue were known only among Asian and African ranoids. Variation in this protuberance among New World dendrobatids and Old World ranids was documented with electron microscopy and four tentative morphologies were described (Type A–D). *Colostethus* exhibits nonretractile protuberances and all examined species except one conform to Type C protuberances, being elongate and longitudinally reclining. The possible function of the median lingual protuberance is discussed, but is still unknown. The authors also describe a new species, *C. atopoglossus,* and discuss the systematics of the genus. These data contribute to our understanding of morphological variation among Neobatrachians, as well as to our understanding of the systematics of this group.

GRANT, T., E. C. HUMPHREY, AND C. W. MYERS. 1998. The median lingual process of frogs: a bizarre character of Old World ranoids discovered in South American dendrobatids. Am. Mus. Novitates 3212:40 pp.

Postfreeze Survival in Wood Frogs

The authors experimentally induced freezing in fall-collected juvenile *Rana sylvatica.* By manipulating the duration of freezing, they found that the percent of frogs that recovered from freezing was reduced as the duration of freezing increased. This may have implications for potential geographic variation in freezing tolerance—frogs in colder climates may be able to survive longer freezing periods. Also, they found that injecting some of the frogs with glucose prior to freezing increased their survival rates. They hypothesize that the major cryoprotectant properties of glucose may not relate to the reduction of ice formation, but rather may act to keep energy levels of frozen tissues high, thereby allowing frozen cells to stay viable for longer periods.

LAYNE, J. R., JR., J. P. COSTANZO, AND R. E. LEE, JR. 1998. Freeze duration influences postfreeze survival in the frog *Rana sylvatica.* J. Exp. Zool. 280:197–201.

Polymorphism and Sex-Specific Fitness Differences in Salamanders

In this paper, Whiteman reports on his study of the facultatively paedomorphic tiger salamander, *Ambystoma tigrinum nebulosum,* in which he recorded life history traits as measures of fitness parameters in several populations. He found that paedomorphic males bred more frequently than metamorphic males, and that there were differences in the sex-ratios among the two morphs—more paedomorphs were male and more metamorphs were female. He suggests that these ratios reflect sex-specific fitness differences consistent with the parental investment theory of Trivers (1972). Because of the unique nature of the environment in these ponds, males are more likely to be paedomorphic and to remain in breeding areas consistently, whereas females are more likely to metamorphose to exploit a variety of resources. Whiteman suggests that the propensity in these salamanders to become paedomorphic relates to sex; therefore, future studies of fitness differences among polymorphic animals should consider each sex separately.

WHITEMAN, H. H. 1997. Maintenance of polymorphism promoted by sex-specific fitness payoffs. Evolution 51:2039–2044.

Intergenic Spacer in Ambystomatid mtDNA

McKnight and Shaffer describe an approximately 240bp long tandem duplicate in the mtDNA (between $tRNA^{Thr}$ and $tRNA^{Pro}$) of ambystomatid salamanders. This region is quite stable, found in all *Ambystoma* surveyed, and quite active—some species have several additional base pairs in this region. They discuss the general features of this intergenic spacer and hypothesize that it may have arisen by a duplication (and editing) event at the 5′ end (including $tRNA^{Thr}$ and $tRNA^{Pro}$ and the control region) early in the origin of this group of salamanders. The authors hypothesize about the possible reasons for the stabitlity of this spacer—either it is because of its strong secondary structure or because it acts as an alternative site of initiation of replication or transcription. They discuss the possible evolution of this sequence within this group (e.g., additional insertion events) and propose that this region may be informative for future work on the phylogenetic relationships of this group, as well as the evolutionary history of this region of mtDNA.

McKnight, M. L., and H. B. Shaffer. 1997. Large, rapidly evolving intergenic spacers in the mitochondrial DNA of the salamander family Ambystomatidae (Amphibia: Caudata). Mol. Biol. Evol. 14:1167–1176.

LETTERS TO THE EDITOR

Quo Vadis? Three American CITES Proposals for American Reptiles

HENRIK BRINGSØE
Esthersvej 7, DK-4600 Køge, Denmark

Before the Tenth Meeting of the Conference of the Parties held in Harare, Zimbabwe, from 9 to 20 June 1997, the United States put forward three proposals for inclusion of North American reptile taxa in CITES Appendix II: *Crotalus horridus, Macroclemys temminckii*, and *Graptemys* spp. For the genus *Graptemys*, the twelve currently recognized species—*barbouri, caglei, ernsti, flavimaculata, geographica, gibbonsi, nigrinoda, oculifera, ouachitensis, pseudogeographica, pulchra,* and *versa*—were included. The subspecies *kohnii* was included within *pseudogeographica*.

In March 1997, I was made aware of the proposals in my position as NGO advisor (representing Nordisk Herpetologisk Forening, the Scandinavian Herpetological Society) for the Danish CITES authority, the National Forest and Nature Agency under the Ministry of the Environment. It was emphasized that these species were in decline, which I have no reason to doubt. However, I was surprised that for nearly all of them the threat was *not* international trade. Rather, the problems were of a domestic nature, typically habitat destruction and various types of uncontrolled hunting or killing. I will briefly go through the main threats to these species; with one exception (Pritchard 1989), all information has been based on the supporting material of the U.S. CITES proposals.

1. *Crotalus horridus.*—The decline over much of the species' range has been caused mainly by habitat loss and destruction as well as collection for rattlesnake roundups. Highway mortality, intentional killing, and collection for commercial pet trade have also been mentioned. Poachers are known to have devastated some populations. However, the international trade in *C. horridus* has been minimal. It certainly does not seem to be very popular among terrarium-keepers or herpetoculturists in Europe.

2. *Macroclemys temminckii.*—This turtle mainly lives in slow-moving rivers, their major tributaries, and associated bodies of water (Pritchard 1989). Much of the natural habitat of the alligator snapping turtle has been eliminated which is by far the most important reason for its decline. A survey in Missouri has revealed that 90% of the habitat now is gone. Pollution is another factor. The U.S. proposal stresses draining of lowlands and swamps, now turned into fields of soybeans and cotton, as an important (perhaps the most important) contribution to the decline of *M. temminckii*.

The most serious utilization of this species is the meat trade for the U.S. market. It is much larger than the pet trade. Especially rapacious has been the Louisiana market for meat. In addition to this commercial trade, *M. temminckii* also is trapped for personal consumption.

For the international pet trade, which has been increasing, mostly juveniles are collected whereas the meat trade utilizes adults which are more valuable for the recovery of natural populations. Although state programs exist for the alligator snapping turtle, no national programs established specifically for the purpose of protecting this species are known.

3. *Graptemys* spp.—It is emphasized that the greatest threat to map turtles is habitat destruction such as alteration of nesting habitats (e.g., waterfront development), water pollution, degradation of waterways, and recreational use of water areas. Basking individuals of many species are shot for target practice. Also, map turtles often are regarded as vermin or at least as competitors for fish. Occasionally humans eat the turtles and their eggs. A number of individuals drown in nets or on trot lines.

Map turtles are popular in the pet trade both domestically and abroad. There is limited captive breeding of some species but most adult captives are wild-caught individuals. Only for *G. barbouri* has the international pet trade been mentioned as a threat to its survival. This species appears to be the one in greatest demand internationally.

None of the three proposals was accepted at the meeting in Harare in June 1997. Those on *C. horridus* and *M. temminckii* were withdrawn, and the one on *Graptemys* spp. was rejected. Appendix III listing, which does not require conference approval, was mentioned as an alternative. But is CITES really an appropriate tool to protect species that suffer from the degradation and reduction of habitats and other domestic abuses?

It is disturbing that the U.S., with its great experience in CITES, has put forward such proposals that do not meet the basic criteria of the convention, i.e., that a species is or may be threatened by international trade. These criteria appear in Article II of the Convention and, in more detail, in Resolution 9.24: "Criteria for Amendment of Appendices I and II" (Resolution of the Conference of the Parties, adopted in Fort Lauderdale, U.S.A., in November 1994). The latter has replaced the Berne Criteria.

Other countries have taken the appropriate measures in their own legislation to prevent habitat destruction and other threats of a national nature. Making such CITES proposals may give an impression that the U.S. Department of the Interior is trying to distract attention from the true cause of these declines. As experienced elsewhere, habitat protection and restoration is costly, but these are virtually the only effective means to correct past mistakes. Of course, it is much easier and less expensive to initiate species protection, regardless of needs for habitat protection! Has the U.S. Department of the Interior taken this step as a feint to show the world that they care about their wildlife?

My intention is *not* to prevent protection of these reptile species. However, the step taken in Harare to reject Appendix II listings was a first signal to the U.S. Department of the Interior to direct their attention to the severe national problems mentioned above and not to blame international trade. It is my firm belief that effective conservation should aim at solving the *real* reasons for the decline, i.e., to initiate an extensive habitat protection program, although it will not at all be as cheap as implementing protection via CITES. CITES listings, including the easy adoption in Appendix III, should be abandoned (except for *G. barbouri*). Furthermore, the awareness of nature protection by the public throughout all social classes in a society is essential to gain wide support. In a civilized and democratic world we will have to accept that the attitude of the public is of utmost importance in conserving nature through habitat protection and prevention of unsustainable hunting and killing.

This case shows that a change of attitude in the U.S. Department of the Interior and perhaps in the U.S. Fish and Wildlife Service, from the dogmatic and conservative view of species protection alone, would be desirable. Perhaps a generational change will be necessary.

I would appreciate it if a representative from the American conservation authorities could present the country's strategy outlining how an *effective* conservation of *C. horridus*, *M. temminckii*, and *Graptemys* spp. can be carried out in order to change the negative development and regain the former status of the populations.

Quo vadis? Where do you go?

POINTS OF VIEW

Bibliographic Accuracy: Importance in Herpetological Publications

ERNEST A. LINER
310 Malibou Boulevard, Houma, Louisiana 70364-2598, USA

and

VICTOR H. HUTCHISON
Department of Zoology, University of Oklahoma
Norman, Oklahoma 73019, USA
e-mail: vhutchison@ou.edu

Bibliographic citations are important sources of information for readers. The accuracy of citations often reflects the care authors have given to their entire paper; inaccurate bibliographies may lead readers to doubt the trustworthiness of authors. Altig (1996) concluded that "from current involvement with large bibliographic listings that at least one-third of the published citations contains errors." One of us (EAL) reviewed over 1000 citations for a bibliography and found at least 20% had errors. Our intent here is to point out many inconsistencies and errors we encountered in compiling bibliographies. As in most fields of knowledge, the now vast herpetological literature appears in many types of publications: newspapers, popular nonscientific and scientific magazines or periodicals, bulletins, journals, occasional papers, proceedings, symposia, reports (business and government), monographs, circulars, and scientific and popular books. Cataloguing these materials into accurate bibliographies can be mind-boggling. Several abstracting services are available such as *Zoological Record, Biological Abstracts, Biologische Zentralblatt, Dissertation Abstracts, Index Medicus, International Abstracts of Biological Sciences, Bibliographie deutschen Zeitschriftenliteratur, Referatvnii Zhurnal,* and *Bulletin Signaletique*. Other good sources are supplied by the journals themselves either on a yearly or other cumulative basis. Some of the herpetological literature does not appear in these standard abstracting sources. As literature increases, some herpetologists have provided valuable service by producing bibliographies on taxonomic units (e.g., *Smithsonian Herpetological Information Service* series, *Catalogue of American Amphibians and Reptiles*), specific topics (e.g., Neill 1958; Harless and Morlock 1973), specific states (e.g., Carpenter and Krupa 1989), countries (e.g., Miyata 1982), geographic regions (e.g., Busack 1976), and habitats (e.g., Neill 1958). One can find errors in most of these bibliographies, even those compiled by abstracting services. The only sure way to provide accurate citations is to check each item directly from the original source. This is virtually an impossible task for editors and many authors who do not have access to large libraries. Even these major depositories will not have everything. A result of these problems is that many references are hand-me-downs copied from other sources. Errors in citations thus become compounded into more errors. With increasing frequency, references are being placed on the Internet by journals, abstracting services, organizations, and individuals. Some of these bibliographies are not checked by an editorial process or by direct reference to the original; errors are likely to be quite common.

We hope that this paper will raise the awareness of the importance of correct citations in herpetological (and other) publications. We believe that the points raised are clearly applicable to most fields of knowledge. Style manuals such as the CBE style manual (Council of Biology Editors 1994) provide guidelines on the preparation of a bibliographic reference under different scenarios. The CBE style manual has been adopted by many biological journals and should be readily available to every writer of biological papers.

We address here each element of a typical bibliographic citation in the order that they most frequently occur in biological publications. Many minor differences exist in the way citations are listed in journals and the style sheet for each journal should be consulted before preparing the literature cited section for a manuscript to be submitted for consideration for publication.

Surname.—This is the last name of the author (first author, if two or more). Errors are quite frequent in the spellings of surnames. Latinized names of a person, particularly in the older literature (e.g., Linné, Linnaeus) are often not treated uniformly. Frequently names are spelled differently for the same person. Russian names frequently are spelled several different ways, often

due to differences in the translation (e.g., -sky vs. -ski or skii; Darevsky, Darevski, Darevskii). One of us (EAL) is working on a massive bibliography (a bibliographic index for the *Biology of the Reptilia*) and found, in several instances, the same reference entered more than once under different spellings or with various prefixes and suffixes to the surname. The use of hyphenated surnames (e.g., Chun-Lee or Chun Lee) can also produce confusion. The example could be listed under C or L for the same person based upon the use of the hyphen. This is frequent in some Asian, Spanish, and English names and is becoming more frequent in the United States where surnames are combined at marriage, either with or without the hyphen. Sometimes authors create problems by not being consistent in use of their hyphenated surname.

Another frequent problem with surnames is the use of da, de, dela, del, van, and von (to name a few), capitalized or not, and sometimes not separated from the surname. Some authors alphabetize under personal-name prefixes followed by whatever name follows. Others use the surname name before the prefix. Some bibliographies list under last names with the prefix first (e.g., Amaral, Alfredo do vs. do Amaral, Alfredo; Wettstein, O. v. vs. von Wettstein, O.). Sometimes this style shows up under both versions in the same publication and leads to duplication in large bibliographic compilations. This problem is compounded by the manner in which nominal prefixes are used in different countries. The simple thing to do is to list under prefixes instead of the body of the last name, but the recommendations in the CBE style manual (Table 7-1, Council of Biology Editors 1994) should be followed.

The use of the umlaut frequently produces problems (e.g., Müller or Mueller for the same author). Inconsistency here leads to duplication in listings and placement in different alphabetical positions. Diacritical marks create a special problem because they are sometimes used and sometimes not, especially in U.S. publications. If the marks are used in the original article, then they should be used in later citations. If both accented and unaccented versions occur in the name of the same author in the original publication or in later listings, the diacritical marks should be added. The accent marks normally do not interfere with alphabetizing, except the umlaut. Where diacritical marks are not available on typewriters or word processors, they should be added by hand to manuscripts. Complete guidelines for proper use of the surname in bibliographic listings are given in the CBE style manual, *The Chicago Manual of Style* (University of Chicago Press 1993), and the *Manual for Preparing Records in Microcomputer-based Bibliographic Information Systems* (Di Lauro and Brandon 1990).

The importance of correctness in the use of names of authors in literature citations goes beyond just the need for accuracy in finding original sources (Garfield 1982). Citation analysis is now widely used for evaluation of the "quality" or "importance" of publications written by faculty members and scientists in governmental and industrial laboratories (Garfield 1988a). The basis of this indicator of productivity is that important papers will be cited more frequently by others. Although obvious limitations exist in this assessment method (Garfield 1988b, 1989; Hutchison 1993; Lindsey 1980), its future use is likely to increase (administrators find numbers easier to use than the more subjective, but often more accurate, verbal descriptions of scientific quality). If authors' names are spelled incorrectly or the wrong initials or given names are used in a citation, the papers will not be included in a citation analysis for an individual, unless such incorrect spellings also are searched in the data banks; these considerations are seldom used. For example, about 40% of the citations to the publications of the second author (VHH) are incorrect (e.g., "Hutchinson" or "Hutcheson" instead of "Hutchison"). In the leading textbook and reference on amphibian biology (Duellman and Trueb 1986), "Hutchinson" appears throughout. Various spellings of the name appear within the same paper (e.g., Dunlap 1989), sometimes on the same page (e.g., Rodríguez et al. 1996), and even within the literature cited section (e.g., Innocenti et al. 1993). Some names are misspelled in the literature cited but do not appear within the text at all (e.g., Luke 1994) or are spelled differently in the text and literature cited section (e.g., Bols et al. 1992). Such errors in books and review papers (e.g., Badia et al. 1993; Bradshaw 1986) are more likely to be perpetuated than incorrect citations in original papers. Thus, authors of books and review papers should take particular care to reduce such errors, but some typographical or other errors are inevitable. Authors should check original sources in all cases.

Copy editors and printers also can contribute to errors in names (e.g., they often believe that "Hutchison" is an error and change it to "Hutchinson"). Errors by printers sometimes occur outside the control of authors, especially where some of the published material is not included with the proofs reviewed by the authors. The authors of *Turtles of the United States and Canada* (1994) are listed incorrectly as Ernst, Barbour, and Lovich on the title page, but the correct order of names (Ernst, Lovich, and Barbour) appears on the dust jacket and on the copyright page with the ISBN number. Such errors may lead to incorrect library listings (e.g., the electronic card catalog at the University of Michigan Libraries has the book correctly under Ernst, Lovich, and Barbour; at Washington University it is Ernst, Barbour, and Lovich).

Given Name.—The current trend in scientific publications is to reduce the length of papers to save on the escalating costs of paper, printing, and distribution. Included within these cost-saving moves is the use of initials only instead of the full first name and middle initial(s). We believe that this is a false economy and leads to many errors in bibliographies. A simple typographical error or an incorrect emendation can lead one astray. Where one initial instead of two or more is used for the same author, listings may appear in incorrect alphabetical order. Sometimes this problem is the result of an author not being consistent in use of initials. The use of the same initials for two or more authors with different names often leads to incorrect multiple listings. Sometimes the correct author(s) can be determined from the time period (e.g., 1800's or 1900's) or subject matter (e.g., anatomy, ecology, systematics). The CBE style manual states that if one or more authors have the same initials with a given surname then the given name should be spelled out; this is rarely done.

Personal-name suffixes (Sr., Jr., II, III, etc.) often produce problems. As with hyphenated surnames, similar problems can occur with given names (e.g., Ming-Chung). Initials of such hyphenated names should include the hyphen (i.e., M-C. for the example given). If two or more persons from the same family are publishing papers, especially in the same field of study, the differences should be shown. When these personal name suffixes are not used, who is the real author? We have found many instances where only the first author is listed alphabetically and then chronologically, with all second coauthors out of alphabetical order. All of the authors' names should be in strict alphabetical order and then in chronological order for papers with the same authors listed in the same order.

Year.—Normally the year of publication is given as printed in the publication. Sometimes the actual date of publication is not as printed but is actually in the following year. For example, the fourth number of a quarterly publication is sometimes delayed up to several months and actually appears in the following year. This can lead to problems, particularly in taxonomy where the actual date of publication determines nomenclatorial priority. Often publications will give the actual date (year) of issue, which should be included within parentheses in a citation [e.g., 1997(1998)]. Frequently the year given for a reference is incorrect, usually an error either in typing or in copying. The use of a, b, c, etc., is used in a given year to designate papers by the same author(s). Errors occur here particularly with multiple authors. Some publications are published in installments that often lead to confusion of the dates of publication. When it is known that a certain installment was actually published then that year should be used. If the date is not known, then hyphenated years should be used (e.g., Günther 1880–1898). The published proceeding of conferences, meetings, and symposia sometimes are published as the date of the meeting and not the date of actual publication. Both dates should be given, but the date of publication should be the one used in bibliographic citations.

Title.—The title should be a simple item to handle in bibliographies, but often it is not. The title should be cited as given in the original paper, but some authors fail to put "The," "An," etc., as the first word. Often words in the title are transposed or words are altered. If an author says the article was in a different language (e.g., Russian), it is understandable that slight differences will show up in translations. Usually this is not a problem but becomes a problem when English titles show up differently in English publications. Articles in edited volumes should always be cited as "*IN: names (ed.), book or volume title, publisher, city of publication, total pages, and pages being cited within the volume.*" All of these elements may not be used by some journals and the order may differ, but the name(s) of the editor(s) and title are essential. These are not always given, making it very difficult to find the original paper or book chapter. Sometimes the portion of a title that follows a colon (or occasionally a period in serially published articles or subtitles of a book) is omitted in bibliographies. As in author names the use of an umlaut can throw a title in a different alphabetical sequence (über vs. ueber). Recently, there has been a tendency to omit material (e.g., order, family) contained in parentheses as part of original article titles. Similarly, when trinomial names are spelled out in the original document, abbreviations should not be used for the specific name in a citation (e.g., *Thamnophis sirtalis sirtalis* in the original source should not be reduced to *Thamnophis s. sirtalis* or *T. s. sirtalis*). When writers copy references from the table of contents of a journal, rather than from the actual article within the issue, errors can be introduced; some journals abbreviate titles, use only initials of authors' names, etc., in the table of contents.

Source.—Common errors in listing the source (publication title or publisher) include the listing of wrong or incomplete information. Such problems often come from the improper use of abbreviations. Preferred citation names and abbreviations are given in *Abbreviated Titles of Biological Journals, The World List of Scientific Periodicals, British Union Catalogue of Periodicals*, and others. The style sheets of many journals specify which standardized list to use, but the abbreviations for most biological journals are quite similar in the guides. For citations to books, the publisher's name usually is given followed by the city of origin. Authors sometimes produce errors by listing the printer, rather than the publisher. The following are good sources for correct citation to books: *British Museum General Catalogue of Printed Books,* Library of Congress's *The National Union Catalogues,* Bowker's *Books in Print,* and similar standard sources available in most major libraries and on the Internet. We warn again that the ideal source for a correct citation is the original itself.

Serial journals usually are issued as a volume or a number. If a publication is issued as a number rather than as a volume, the issue number should be in parentheses. When parentheses are not used, wrong numbers often are given for the publication. Wrong volume numbers are listed often, sometimes with obviously transposed numbers or typographical errors; other errors are sometimes not so obvious. Some journals (e.g., *Copeia)* do not have volume numbers; in such cases the year of issue should be used as the volume. Where a journal has several issues a year, each issue usually is numbered and often included in parentheses following the volume number. As with other elements of citations, some journals now omit the issue number as another "economy." Wrong issue numbers occur frequently. Page numbers follow, and are separated from the volume and issue numbers, usually by a colon or a comma. Many errors occur in the pagination portion of citations. Authors sometimes do not cite a fractional page at the end of an article or will include a blank page behind an article or give incorrect pagination. Plates or appendixes at the end of an article should be included as part of the pagination or added after the pagination if the publication used Roman numerals for the appended material. Occasionally, only the first page of an article is given; this can lead to problems when one orders photocopies through an interlibrary loan or tries to track down original materials. For these reasons we abhor the tendency of some current journals (e.g., *Science*) to save space by using only the first page numbers of articles listed in the literature cited section.

Ethics and Professionalism.—We have encountered all of the above problems (and others not discussed) in compilations of several bibliographies from multi-volume works. Checking every reference from its original source is not always possible. Anytime a reference appears with different versions, the only *sure* way to find the correct version is to check the original citation. The failure to consult original articles, especially those cited in research papers and reviews, is unprofessional. When one deals with thousands of references on a variety of subjects, the determination of the correctness of citations can be extremely time-consuming. In one case a reference was listed five times. The first four were identical so one might assume that it was correct. The fifth occurrence had some variances; it was checked and found to be correct. The first four were wrong!

Many problems emerge from citations listed as "in press," "in manuscript," "submitted," and "in preparation." Occasionally the journal listed in a citation as "in press" had no such article published several years before or after the date of the citation. The cited manuscript either was withdrawn, anticipated but never submitted, or was submitted and then rejected by the journal. Sometimes the article was in a journal other than the one cited, and sometimes with additional authors. Occasionally we found after checking all available sources that the article never was published. Such misuses of "in press" are clearly unethical. Reviewers and editors have a duty to help ensure that such abuses do not occur.

Authors appear to be increasingly careless in citing publications that they have not seen and are simply copying the references from other sources. Resultant errors then are made worse

by additional mistakes and, in time, through aggregation of these errors, a citation may become quite distinct from the original. When it is impossible or impractical to consult an original reference as cited in a subsequent document, the original full citation should be given, followed by "cited in" and the name and date for the secondary source (e.g., "Jones 1952, cited in Smith 1978"). Authors sometimes are careless in citing even with the original paper in hand, and sometimes incorrectly cite their own papers! It falls upon the author to be more careful; editors and reviewers cannot check out every reference from its original source, particularly with very lengthy bibliographies.

Conclusion.—Although the errors of existing bibliographies are now history, we hope that this summation of some common problems will lead to renewed vigilance on the part of authors, reviewers, and editors, and the incidence of errors will decline. We know that we have made some of the same errors we have discussed, but we will be monitoring our own bibliographic citations more carefully in the future.

Acknowledgments.—We thank Ronn Altig , Bill Boarman, and Jeffrey Lovich for suggestions and review of the manuscript.

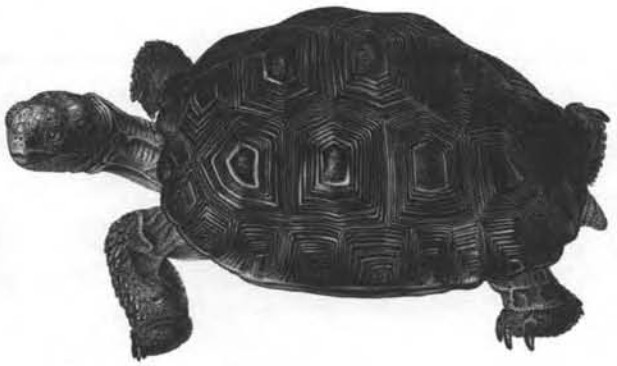
Two New Facsimile Reprints from the Society for the Study of Amphibians and Reptiles

CONTRIBUTIONS TO THE HERPETOLOGY OF THE *BELGIAN CONGO*



Karl P. Schmidt and G. K. Noble

New introductions by
Donald G. Broadley and John C. Poynton

THIS CLASSIC SERIES, ORIGINALLY PUBLISHED IN 1919–1923 in three volumes, is the most comprehensive work on the herpetology of Central Africa and still an essential reference for the Congo rain forest and the Sudanese savanna. A total of 133 species of reptiles and 56 of amphibians are covered. The extensive new introductions by Donald Broadley and John Poynton, who are acknowledged authorities on the herpetofauna of sub-Saharan Africa, include the current nomenclature for Schmidt's and Noble's names, biogeographic analyses, and bibliographies of Congo herpetology to update those in the original books.

Specifications: 780 pages, 141 photographs, many text figures, indices, clothbound with dust jacket, ISBN 0–916984–45–1. To be issued September 1998.

THE GIGANTIC LAND TORTOISES

OF THE GALAPAGOS ARCHIPELAGO

John VanDenburgh

Foreword by Peter C. H. Pritchard

THIS BOOK IS THE MOST EXTENSIVE REVIEW OF THE giant tortoises of the Galapagos Islands. It contains detailed descriptions of 266 specimens collected by the California Academy of Sciences expedition of 1905–1906, as well as extensive field notes by the collectors, tables of measurements of shells and eggs, and 200 photographs of tortoises. The new foreword by Peter Pritchard, who is himself a specialist on Galapagos tortoises, includes the current nomenclature for VanDenburgh's names and a summary of the expedition with contemporary photographs and new map.

Specifications: 290 pages, 205 photographs, index, clothbound with dust jacket, ISBN 0–916984–46–X. To be issued September 1998.
